

PCM1733

SoundPLUS™ Stereo Audio
DIGITAL-TO-ANALOG CONVERTER
18 Bits, 96kHz Sampling

FEATURES

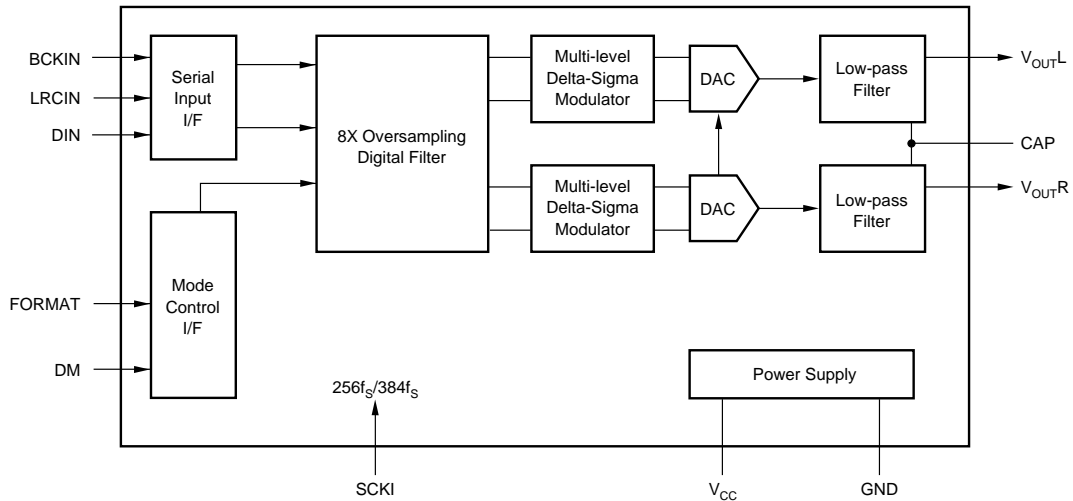

- **COMPLETE STEREO DAC:** Includes Digital Filter and Output Amp
- **DYNAMIC RANGE:** 95dB
- **MULTIPLE SAMPLING FREQUENCIES:** 16kHz to 96kHz
- **8X OVERSAMPLING DIGITAL FILTER**
- **SYSTEM CLOCK:** 256f_s/384f_s
- **NORMAL OR I²S DATA INPUT FORMATS**
- **SMALL 14-PIN SOIC PACKAGE**

DESCRIPTION

The PCM1733 is a complete low cost stereo audio digital-to-analog converter (DAC), operating off of a 256f_s or 384f_s system clock. The DAC contains a 3rd-order ΔΣ modulator, a digital interpolation filter, and an analog output amplifier. The PCM1733 accepts 18-bit input data in either normal or I²S formats.

The digital filter performs an 8X interpolation function and includes de-emphasis at 44.1kHz. The PCM1733 can accept digital audio sampling frequencies from 16kHz to 96kHz, always at 8X oversampling.

The PCM1733 is ideal for low-cost, CD-quality consumer audio applications.

NOTES: (1) Schmitt Trigger input. (2) Schmitt Trigger input with internal pull-up.

ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

TYPICAL PERFORMANCE CURVES

At $T_A = +25^\circ\text{C}$, $V_{CC} = +5\text{V}$, $f_s = 44.1\text{kHz}$, $\text{SYSCLK} = 256f_s$, unless otherwise noted.

DYNAMIC PERFORMANCE

TYPICAL PERFORMANCE CURVES

At $T_A = +25^\circ\text{C}$, $+V_{CC} = +V_{DD} = +5\text{V}$, $f_S = 44.1\text{kHz}$, and 18-bit input data, $\text{SYSCLK} = 384f_S$, unless otherwise noted.

DIGITAL FILTER

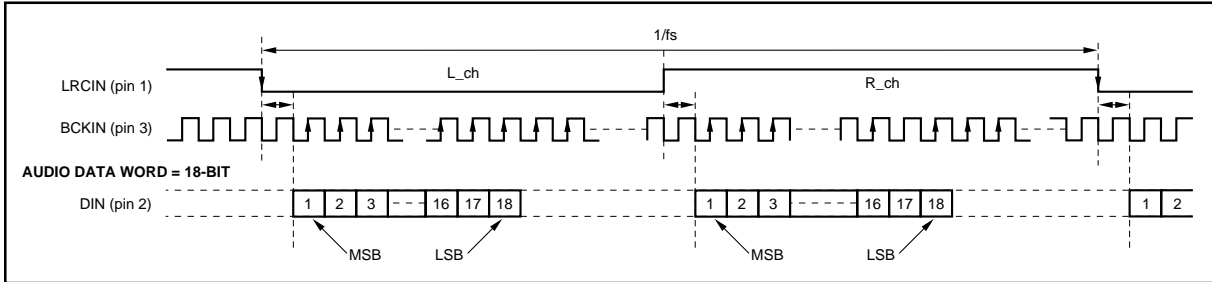

FIGURE 2. "I²S" Data Input Timing.

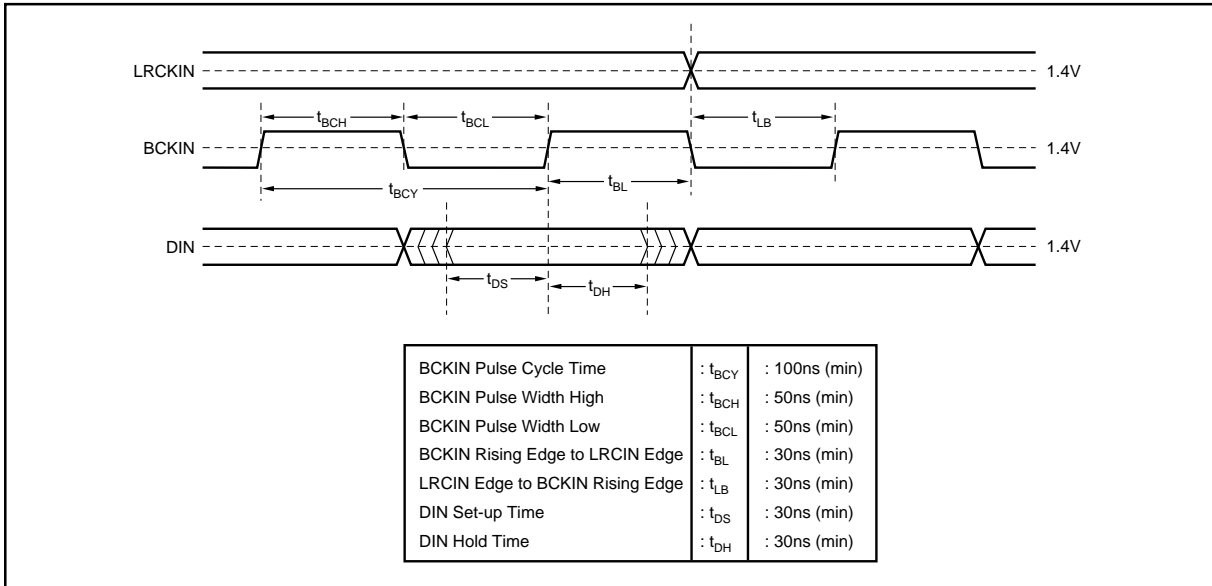

FIGURE 3. Audio Data Input Timing.

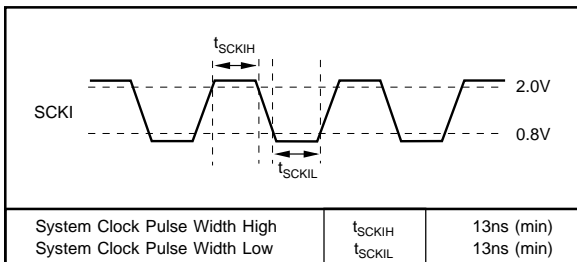

FIGURE 4. System Clock Timing Requirements.

SYSTEM CLOCK

The system clock for PCM1733 must be either $256f_s$ or $384f_s$, where f_s is the audio sampling frequency (LRCIN), typically 32kHz, 44.1kHz or 48kHz. The system clock is used to operate the digital filter and the noise shaper. The system clock input (SCKI) is at pin 14. Timing conditions for SCKI are shown in Figure 4.

PCM1733 has a system clock detection circuit which automatically detects the frequency, either $256f_s$ or $384f_s$. The system clock should be synchronized with LRCIN (pin 1), but PCM1733 can compensate for phase differences. If the phase difference between LRCIN and system clock is greater than ± 6 bit clocks (BCKIN), the synchronization is performed automatically. The analog outputs are forced to a bipolar zero state ($V_{CC}/2$) during the synchronization function. Table I shows the typical system clock frequency inputs for the PCM1733.

SAMPLING RATE (LRCIN)	SYSTEM CLOCK FREQUENCY (MHz)	
	$256f_s$	$384f_s$
32kHz	8.192	12.288
44.1kHz	11.2896	16.9340
48kHz	12.288	18.432

TYPICAL CONNECTION DIAGRAM

Figure 5 illustrates the typical connection diagram for PCM1733 used in a stand-alone application.

INPUT DATA FORMAT

PCM1733 can accept input data in either normal (MSB-first, right-justified) or I²S formats. When pin 13 (FORMAT) is LOW, normal data format is selected; a HIGH on pin 13 selects I²S format.

FORMAT	
0	Normal Format (MSB-first, right-justified)
1	I ² S Format (Philips serial data protocol)

TABLE II. Input Format Selection.

RESET

PCM1733 has an internal power-on reset circuit. The internal power-on reset initializes (resets) when the supply voltage $V_{CC} > 2.2V$ (typ). The power-on reset has an initialization period equal to 1024 system clock periods after $V_{CC} > 2.2V$. During the initialization period, the outputs of the DAC are invalid, and the analog outputs are forced to $V_{CC}/2$. Figure 6 illustrates the power-on reset and reset-pin reset timing.

DE-EMPHASIS CONTROL

Pin 12 (DM) enables PCM1733's de-emphasis function. De-emphasis operates only at 44.1kHz.

DM	
0	De-emphasis OFF
1	De-emphasis ON (44.1kHz)

APPLICATION CONSIDERATIONS

DELAY TIME

There is a finite delay time in delta-sigma converters. In A/D converters, this is commonly referred to as latency. For a delta-sigma D/A converter, delay time is determined by the order number of the FIR filter stage, and the chosen sampling rate. The following equation expresses the delay time of PCM1733:

$$T_D = 11.125 \times 1/f_S$$

$$\text{For } f_S = 44.1\text{kHz, } T_D = 11.125/44.1\text{kHz} = 251.4\mu\text{s}$$

Applications using data from a disc or tape source, such as CD audio, CD-Interactive, Video CD, DAT, Minidisc, etc., generally are not affected by delay time. For some professional applications such as broadcast audio for studios, it is important for total delay time to be less than 2ms.

OUTPUT FILTERING

For testing purposes all dynamic tests are done on the PCM1733 using a 20kHz low pass filter. This filter limits the measured bandwidth for THD+N, etc. to 20kHz. Failure to use such a filter will result in higher THD+N and lower SNR and Dynamic Range readings than are found in the specifications. The low pass filter removes out of band noise. Although it is not audible, it may affect dynamic specification numbers.

The performance of the internal low pass filter from DC to 24kHz is shown in Figure 7. The higher frequency rolloff of the filter is shown in Figure 8. If the user's application has the PCM1733 driving a wideband amplifier, it is recommended to use an external low pass filter. A simple 3rd-order filter is shown in Figure 9. For some applications, a passive RC filter or 2nd-order filter may be adequate.

BYPASSING POWER SUPPLIES

The power supplies should be bypassed as close as possible to the unit. It is also recommended to include a 0.1μF ceramic capacitor in parallel with the 10μF tantalum bypass capacitor.

FIGURE 9. 3rd-Order LPF.

FIGURE 10. 5-Level $\Delta\Sigma$ Modulator Block Diagram.

THEORY OF OPERATION

The delta-sigma section of PCM1733 is based on a 5-level amplitude quantizer and a 3rd-order noise shaper. This section converts the oversampled input data to 5-level delta-sigma format. A block diagram of the 5-level delta-sigma modulator is shown in Figure 10. This 5-level delta-sigma modulator has the advantage of stability and clock jitter over the typical one-bit (2-level) delta-sigma modulator.

The combined oversampling rate of the delta-sigma modulator and the internal 8X interpolation filter is $96f_s$ for a $384f_s$ system clock, and $64f_s$ for a $256f_s$ system clock. The theoretical quantization noise performance of the 5-level delta-sigma modulator is shown in Figure 11.
