

GENERAL DESCRIPTION

The SM5804 Series is manufactured using MOLYGATE (モリゲート®) CMOS technology developed by NPC and is implemented in 4 times oversampling digital filter technique with high stopband attenuation and low passband ripple for CD player applications. This device contains digital filters for two channels and the 4 times oversampling output can be obtained from each channel so that the last stage lowpass filter can be simplified. The input and output data can be externally selected to be either serial or parallel which reduces system design restrictions. The SM5804 series has four types, Type A through Type D, classified by the filter characteristics and input data timing.

FEATURES

- Filter Structure
 - Dual channel filters
 - 4 times oversampling
 - Two cascaded linear phase FIR filters (80taps + 15taps)
 - 18-bit filter coefficients and 25-bit accumulator (less round-off error)
 - 16 X 18-bit multiplier
 - Overflow limiter

Filter Characteristics

		Type A	Type B, C, and D
Passband ripple (0 ~ 20KHz)		≤ ±0.09dB	≤ ±0.015dB
Stopband attenuation	24.1 ~ 64.1KHz	≥ 90dB	≥ 70dB
	64.1KHz ~	≥ 70dB	≥ 70dB

- Compensated 3rd order Bessel filter (for type C only)
- D/A converter aperture time error correction
- Linear phase
- Input/Output
 - 16-bit serial or parallel input and output modes
 - MSB first-in/out or LSB first-in/out modes
 - 2's complement or offset binary input and output format
- Power Supply 5V ±10%
- TTL Compatible (Input and Output)
- 60-Pin Flat Package
- MOLYGATE CMOS Technology

INTRODUCTION

Basic Filter Structure

The SM5804 series consists of two channel filters implemented in two times oversampling two stages cascaded linear phase FIR filter as shown in Fig. 1. The 44.1KHz sampled signal is two times oversampled in the 80-tap first filter stage and is converted to a 88.2KHz sampled signal. It is further two times oversampled in the 15-tap second filter stage and becomes 176.4KHz sampled signal which is 4 times oversampled as compared with that at the input.

Fig. 2 illustrates sampled signal spectrum of the output of channel filter (see Fig. 1) in various configurations. Fig. 2(a) shows the output spectra of the first filter which provides -90dB or -70dB attenuation at and above 24.1KHz in Type A or Type B, C and D configuration respectively. However, the input signal spectrum of ± 24.1 KHz centered on 88.2KHz sampling frequency still exists. The second filter which further doubles the sampling frequency for filtering the output of the first filter provides -70dB attenuation for the signal band between 64.1KHz and 112.3KHz as shown in Fig. 2(b). The combined filter characteristics of Type A and Type B, C and D are illustrated in Fig. 2(c) and (d) respectively. A simple 3rd order active lowpass filter may be used as a postfilter following the SM5804 second filter stage. The SM5804 series are designed based on this oversampling technique and their filter characteristics are illustrated in page 2 through 5.

Block Diagram

Fig. 3 is SM5804 series filter block diagram. Two channel filters, Ach and Bch operate independently and their inputs and outputs can also be independently selected to operate in serial or parallel mode.

Application Examples

As the input and output can be independently selected for serial/parallel mode, the external DAC which follows the SM5804 can also be connected in various ways. Six examples are illustrated in Fig. 4.

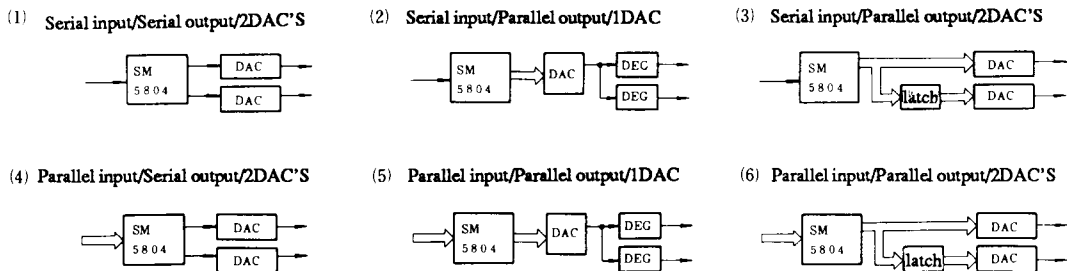

Figure 4 Applications

FUNCTIONAL DESCRIPTION

(1) Serial/Parallel mode select

Input and output data can be independently selected to either serial mode or parallel mode through $\overline{\text{PISL}}$ and $\overline{\text{POSL}}$ respectively.

Input:	$\overline{\text{PISL}} = \text{H}$ (or open)	Serial Input
	$\overline{\text{PISL}} = \text{L}$	Parallel Input
Output:	$\overline{\text{POSL}} = \text{H}$ (or open)	Serial Output
	$\overline{\text{POSL}} = \text{L}$	Parallel Output

(2) 2's Complement/Offset binary code select

Input and output data format can be independently selected to either 2's complement or offset binary through $\overline{\text{XOFB}}$ and $\overline{\text{YOFB}}$.

Input:	$\overline{\text{XOFB}} = \text{H}$ (or open)	2's complement
	$\overline{\text{XOFB}} = \text{L}$	offset binary
Output:	$\overline{\text{YOFB}} = \text{H}$ (or open)	2's complement
	$\overline{\text{YOFB}} = \text{L}$	offset binary

(3) Ach and Bch Data synchronization

One frame of the input sampled data (consisting of Ach and Bch data) is processed simultaneously. Therefore, synchronization of the Ach and Bch input data pair is necessary to avoid phase difference between two channels due to the different sampling time slot. Pin $\overline{\text{ABSL}}$ is provided to synchronize Ach and Bch data to either rising or falling edge of the synchronization clock (44CI, 44.1KHz) to prevent channel phase difference. However, if $\overline{\text{SIEA}}$ and $\overline{\text{SIEB}}$ are used for serial input mode, $\overline{\text{ABSL}}$ pin can be ignored.

Figure 5 Clock and Data Timing Waveforms

(4) Phase Relation between 44CI and XT clocks

The system clock XT must stay "high" for 30ns before and 5ns after the rising transition (when $\overline{\text{ABSL}}=\text{H}$) or the falling transition (when $\overline{\text{ABSL}}=\text{L}$) of the synchronization clock 44CI. i.e. The shaded area of the Fig. 6 must fall within the "high" cycle of clock XT.

Figure 6 44CI and XT Clocks Timing Waveforms

(5) Serial input mode ($\overline{\text{PISL}} = \text{H}$ or open)

The following steps/conditions apply to serial input mode operation.

- (i) Connect input data line to Pin SID.
- (ii) Read timing is selected by applying "H" or "L" voltage level to Pin $\overline{\text{SIMD}}$.

- When $\overline{\text{SIMD}} = \text{H}$ or open

In this mode, serial input bit clock, BCKI, and Ach and Bch serial input enables $\overline{\text{SIEA}}$ and $\overline{\text{SIEB}}$ are involved. The data is clocked into the shift register at the rising edge of BCKI while $\overline{\text{SIEA}}$ and $\overline{\text{SIEB}}$ are at "L". It is therefore required that changing of data state must take place at the falling edge of BCKI. Data will be transferred and latched in parallel into other registers at the falling edge of $\overline{\text{SIEA}}$ or $\overline{\text{SIEB}}$ after the 16-bit data has been read.

- When $\overline{\text{SIMD}} = \text{L}$

In this mode, serial input bit clock, BCKI, and 44CI clock are involved. The data is clocked into the shift register at the rising edge of BCKI and the change of data state is allowed at falling edge of BCKI. Data will be transferred and latched in parallel by the 44CI clock at either rising or falling edge of the clock.

(iii) MSB first-in/LSB first-in select

MSB first-in or LSB first-in is selected by using the $\overline{\text{LSBI}}$ pin as follows:

$\overline{\text{LSBI}} = \text{H}$ or open,	MSB first-in
$\overline{\text{LSBI}} = \text{L}$,	LSB first-in

NOTE: In serial input mode, X7 through X16 pins are not used. However, any interference to these pins does not effect performance and accuracy of the device.

(6) Parallel input mode ($\overline{\text{PISL}} = \text{L}$)

The following steps/conditions apply to parallel input mode operation.

- (i) Connect input data lines to Pin X1 through X16 (X1 = LSB, X16 = MSB).
- (ii) Connect 44.1KHz (50% duty cycle) synchronization clock to Pin 44CI.

Figure 7 Input, Output and Clock Timing Waveforms.

(iii) Read timing

Ach and Bch parallel data are read at the second falling edge of the system clock, XT (approx. 4MHz) after the transition of the synchronization clock, 44CI. See Fig. 8.

Figure 8 Sync clock, System Clock and Output Timing Waveforms.

(7) Data processing starting timing

When the input data is in parallel or serial mode with $\overline{\text{SIMD}} = \text{L}$, the data processing starts at the rising edge of 44CI for $\overline{\text{ABS}}\text{L} = \text{H}$ or open, or the falling edge of 44CI for $\overline{\text{ABS}}\text{L} = \text{L}$

When the input data is in serial mode with $\overline{\text{SIMD}} = \text{H}$ or open, the data processing starts at the rising edge of $\overline{\text{SIEB}}$.

(8) Serial output mode ($\overline{\text{POS}}\text{L} = \text{H}$ or open, $\overline{\text{SOMD}} = \text{L}$)

The following conditions apply to serial output mode operation.

(i) Serial output data for Ach and Bch are available at SODA and SODB respectively. Serial output data is synchronized to the falling edge of the output bit clock running at the same frequency of system clock.

(ii) MSB first-out/LSB first-out select

MSB first-out or LSB first-out mode can be selected by Pin $\overline{\text{LSB}}\text{O}$.

MSB first-out $\overline{\text{LSB}}\text{O} = \text{H}$ or OPEN

LSB first-out $\overline{\text{LSB}}\text{O} = \text{L}$

In the serial output mode, $\overline{\text{Y}}10 \sim \overline{\text{Y}}16$ pins are not used and stay at high impedance state.

(9) Parallel output mode ($\overline{\text{POS}}\text{L} = \text{L}$)

The following conditions apply to parallel output mode operation.

(i) Parallel data outputs are available at $\overline{\text{Y}}1 \sim \overline{\text{Y}}16$ pins ($\overline{\text{Y}}1 = \text{LSB}$, $\overline{\text{Y}}16 = \text{MSB}$)

(ii) Pin $\overline{\text{POMD}}$ provides the options for the number of DAC to be connected.

$\overline{\text{POMD}} = \text{H}$ or open One DAC application

$\overline{\text{POMD}} = \text{L}$ Two DAC's in phase conversion application. See Fig. 1, page 14 for circuit connection.

(10) DAC control signal

DGA, DGB as well as CO1 - CO4 are used as control signals for DAC.

The following pin combinations are defined for different selected output modes.

In serial output mode, use Pin CO1~CO4, DGA and DGB.

In parallel output mode, use Pin DGA and DGB.

Refer to the operation mode table, Table 1 on page 11 for details.

(11) Input and Output time delay

See page 11 for details.

OPERATING MODES TABLE

Table 1 Input and Output Modes Selection

- *1 Input and output modes can be selected independently.
- *2 "H" means connected to VDD or open.

System Clock Selections

SM5804 Series operates with a clock frequency of 96fs=4.2336MHz or 98fs=4.3218MHz (fs is sampling frequency) and Pin 4SSL is normally at "H" or open. Pin CKSL is to select external clock or crystal oscillator to the device. However, external clock can be connected through crystal oscillator pins. In case of sharing the clock with μP or DAC, set Pin 4SSL, CKSL, SCSL voltage levels according to Table 2 for the correct clock frequency.

4SSL and clock origin	4SSL="H" (or Open)		4SSL="L"	
	external clock	external clock	external clock	external clock
SCSL	CKSL="H" 4.2336MHz (96fs)	CKSL="L" 4.3218MHz (98fs)	CKSL="H" 8.4672MHz (192fs)	CKSL="L" 8.6436MHz (196fs)
XT, XT clock output (CKO) system clock (internal)	SCSL="H" 4.2336MHz (96fs)	SCSL="L" 4.3218MHz (98fs)	SCSL="H" 8.4672MHz (192fs)	SCSL="L" 8.6436MHz (196fs)

Table 2 System Clock Selections

SM5804

- Output to Input Delay Time
There is a time delay between output data frame and input data frame due to the time required for data processing. This delay time, TOF is defined in Fig. 9.

Figure 9 Input and Output Word Frames

- Synchronization of frame data

In order to process the in phase data as a frame, Pin ABSL sets Ach and Bch data pair synchronization to either rising or falling edge of 44CI as shown in Figure 10.
