# Notes on SLA7000/SMA7000 Series

## ■Features

- Employs a constant-current chopper control method.
- Integrates power MOSFETs and monolithic chip control circuitry in a single package.
- One-fifth the size and one-fourth the power dissipation compared with conventional SANKEN ICs

### Comparison of power dissipation.

- Eliminates the need for heatsink thereby decreasing part-insertion workload and increasing flexibility in mounting.
- Reduces the size of power supplies required.
- Lineup: 2-phase excitation, 2-phase/1-2 phase excitation, 2W1-2 phase micro-step support ICs

## ■Applications

The SLA7000 and SMA7000 series are ideal for the following applications.

- Sheet feeders and carriage drivers in printers.
- Sheet feeders for PPC and facsimile machines.
- Numeric control equipment.
- Industrial robots.

## ■Handling Precautions

- Recommended screw torque  
0.588 to 0.784 [N•m](6.0 to 8.0 [kgf•cm])
- Recommended silicon grease  
Shin-Etsu Chemical Co., Ltd.: G746  
GE Toshiba Silicone Co., Ltd.: YG-6260  
Dow Corning Toray Silicone Co., Ltd.: SC102  
Please be careful when selecting silicone grease since the oil in some grease may penetrate the product, which will result in an extremely short product life.

## ■Constant Current Chopper Method

In the constant current chopper method, a voltage higher than the rated voltage of the motor is applied and when the current rises, the chopper transistor is switched on thereby shortening the current rise time. After the current rises, the coil current is held by the PWM chopper to a constant current level determined by the current sense resistor. This method has the advantage of improving the motor's high frequency response and the efficiency response and efficiency of the driver circuitry.

# Application Notes

## Determining the Output Current

Fig. 1 shows the waveform of the output current (motor coil current). The method of determining the peak value of the output current ( $I_o$ ) based on this waveform is shown below.

(Parameters for determining the output current  $I_o$ )

- $V_b$ : Reference supply voltage
- $r_1, r_2$ : Voltage-divider resistors for the reference supply voltage
- $R_s$ : Current sense resistor

### (1) Normal rotation mode

$I_o$  is determined as follows when current flows at the maximum level during motor rotation. (See Fig.2.)

$$I_o \cong \frac{r_2}{r_1+r_2} \cdot \frac{V_b}{R_s} \dots\dots\dots (1)$$

### (2) Power down mode

The circuit in Fig.3 ( $r_x$  and  $T_r$ ) is added in order to decrease the coil current.  $I_o$  is then determined as follows.

$$I_{OPD} \cong \frac{1}{1 + \frac{r_1(r_2+r_x)}{r_2 \cdot r_x}} \cdot \frac{V_b}{R_s} \dots\dots\dots (2)$$

Equation (2) can be modified to obtain equation to determine  $r_x$ .

$$r_x = \frac{1}{\frac{1}{r_1} \left( \frac{V_b}{R_s \cdot I_{OPD}} - 1 \right) - \frac{1}{r_2}}$$

Fig. 4 and 5 show the graphs of equations (1) and (2) respectively.

**(NOTE)**

Ringing noise is produced in the current sense resistor  $R_s$  when the MOSFET is switched ON and OFF by chopping. This noise is also generated in feedback signals from  $R_s$  which may therefore cause the comparator to malfunction. To prevent chopping malfunctions,  $r_5(r_6)$  and  $C_3(C_4)$  are added to act as a noise filter.

However, when the values of these constants are increased, the response from  $R_s$  to the comparator becomes slow. Hence the value of the output current  $I_o$  is somewhat higher than the calculated value.

**Determining the chopper frequency**

Determining T<sub>OFF</sub>

The SLA7000M and SMA7000M series are self-excited choppers. The chopping OFF time T<sub>OFF</sub> is fixed by r<sub>3</sub>/C<sub>1</sub> and r<sub>4</sub>/C<sub>2</sub> connected to terminal Td.

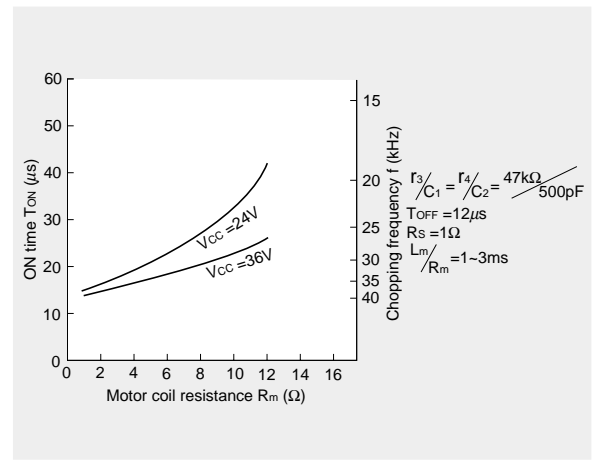

T<sub>OFF</sub> can be calculated using the following formula:

$$T_{OFF} \approx -r_3 \cdot C_1 \ln\left(1 - \frac{2}{V_b}\right) = -r_4 \cdot C_2 \ln\left(1 - \frac{2}{V_b}\right)$$

The circuit constants and the T<sub>OFF</sub> value shown below are recommended.

T<sub>OFF</sub> = 12μs at r<sub>3</sub>=47kΩ, C<sub>1</sub>=500pF, V<sub>b</sub>=5V

**Fig. 6 Chopper frequency vs. Motor coil resistance**

**Chopper frequency vs. Supply voltage**

**Chopper frequency vs. Output current**

**Thermal Design**

An outline of the method for calculating heat dissipation is shown below.

(1) Obtain the value of  $P_H$  that corresponds to the motor coil current  $I_o$  from Fig. 7 "Heat dissipation per phase  $P_H$  vs. Output current  $I_o$ ."

(2) The power dissipation  $P_{diss}$  is obtained using the following formula.

2-phase excitation:  $P_{diss} \cong 2P_H + 0.015 \times V_s$  (W)

1-2 phase excitation:  $P_{diss} \cong \frac{3}{2} P_H + 0.015 \times V_s$  (W)

(3) Obtain the temperature rise that corresponds to the calculated value of  $P_{diss}$  from Fig. 8 "Temperature rise."

**Fig. 7 Heat dissipation per phase  $P_H$  vs. Output current  $I_o$**

**Fig. 8 Temperature rise**

## ■Outline

SMA7036M is a stepper motor driver IC developed to reduce the number of external parts required by the conventional SMA7029M. This IC successfully eliminates the need for some external parts without sacrificing the features of SMA7029M. The basic function pins are compatible with those of SMA7029M.

## ■Notes on Replacing SMA7029M

SMA7036M is pin-compatible with SMA7029M. When using the IC on an existing board, the following preparations are necessary:

- (1) Remove the resistors and capacitors attached for setting the chopping OFF time. ( $r_3$ ,  $r_4$ ,  $C_1$ , and  $C_2$  in the catalog)
- (2) Remove the resistors and capacitors attached for preventing noise in the detection voltage  $V_{RS}$  from causing malfunctioning and short the sections from which the resistors were removed using jumper wires. ( $r_5$ ,  $r_6$ ,  $C_3$ , and  $C_4$  in the catalog)
- (3) Normally, keep pins 2 and 11 grounded because their functions have changed to synchronous and asynchronous switching (SYNC terminals). For details, see "Circuit for Preventing Abnormal Noise When the Motor Is Not Running (Synchronous circuit)." (Low: asynchronous, High: synchronous)

## ■Circuit for Preventing Abnormal Noise When the Motor Is Not Running (Synchronous Circuit)

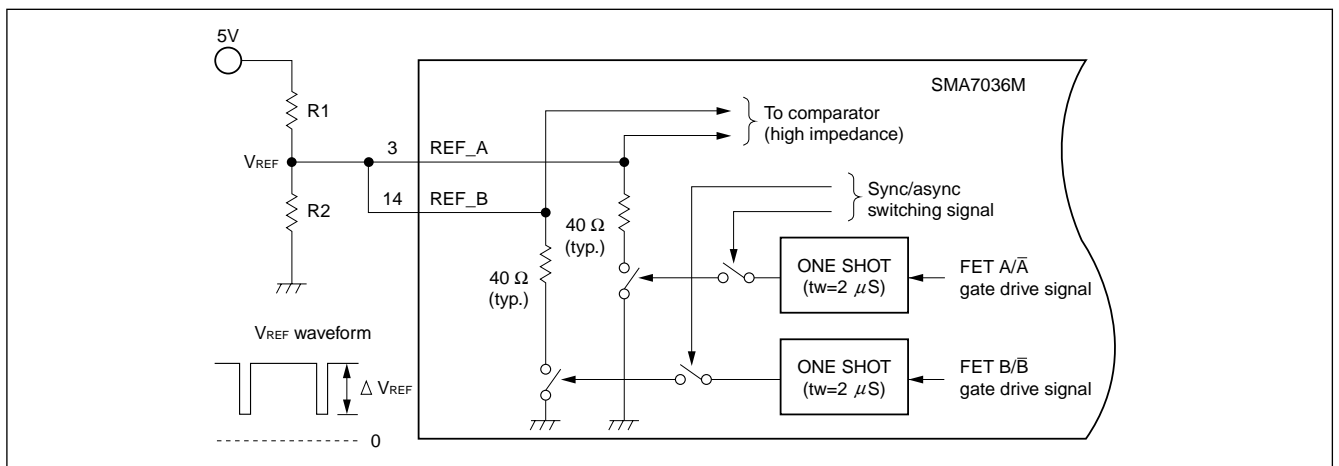

A motor may generate abnormal noise when it is not running. This phenomenon is attributable to asynchronous chopping between phases A and B. To prevent the phenomenon, SMA7036M contains a synchronous chopping circuit. Do not leave the SYNC terminals open because they are for CMOS input.

Connect TTL or similar to the SYNC terminals and switch the SYNC terminal level high or low.

When the motor is not running, set the TTL signal high (SYNC terminal voltage: 4 V or more) to make chopping synchronous. When the motor is running, set the TTL signal low (SYNC terminal voltage: 0.8 V or less) to make chopping asynchronous. If chopping is set to synchronous when the motor is running, the motor torque deteriorates before the coil current reaches the set value. If no abnormal noise occurs when the motor is not running, ground the SYNC terminals (TTL not necessary).

The built-in synchronous chopping circuit superimposes a trigger signal on the REF terminal for synchronization between the two phases. The figure below shows the internal circuit of the REF terminal. Since the  $\Delta V_{REF}$  varies depending on the values of R1 and R2, determine these values for when the motor is not running within the range where the two phases are synchronized.

**Determining the Output Current**

Fig. 1 shows the waveform of the output current (motor coil current). The method of determining the peak value of the output current ( $I_o$ ) based on this waveform is shown below.

(Parameters for determining the output current  $I_o$ )

- $V_b$ : Reference supply voltage
- $r_1, r_2$ : Voltage-divider resistors for the reference supply voltage
- $R_s$ : Current sense resistor

(1) Normal rotation mode

$I_o$  is determined as follows when current flows at the maximum level during motor rotation. (See Fig.2.)

$$I_o \cong \frac{r_2}{r_1+r_2} \cdot \frac{V_b}{R_s} \dots\dots\dots (1)$$

(2) Power down mode

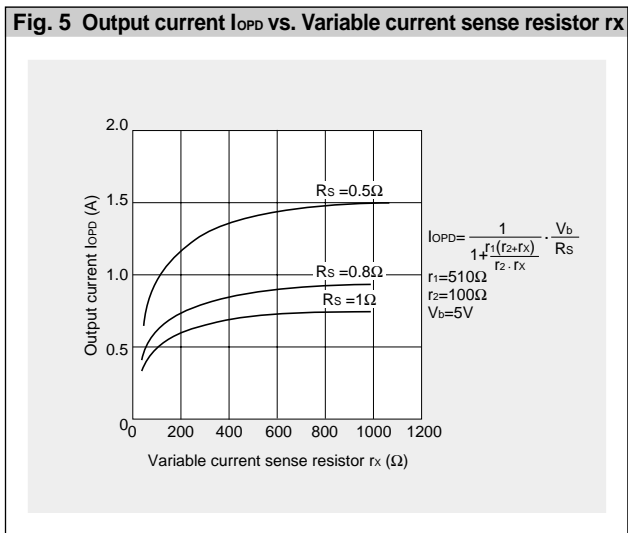

The circuit in Fig.3 ( $r_x$  and  $T_r$ ) is added in order to decrease the coil current.  $I_{OPD}$  is then determined as follows.

$$I_{OPD} \cong \frac{1}{1 + \frac{r_1(r_2+r_x)}{r_2 \cdot r_x}} \cdot \frac{V_b}{R_s} \dots\dots\dots (2)$$

Equation (2) can be modified to obtain equation to determine  $r_x$ .

$$r_x = \frac{1}{\frac{1}{r_1} \left( \frac{V_b}{R_s \cdot I_{OPD}} - 1 \right) - \frac{1}{r_2}}$$

Fig. 4 and 5 show the graphs of equations (1) and (2) respectively.

**Thermal Design**

An outline of the method for calculating heat dissipation is shown below.

- (1) Obtain the value of  $P_H$  that corresponds to the motor coil current  $I_o$  from Fig. 6 "Heat dissipation per phase  $P_H$  vs. Output current  $I_o$ ."

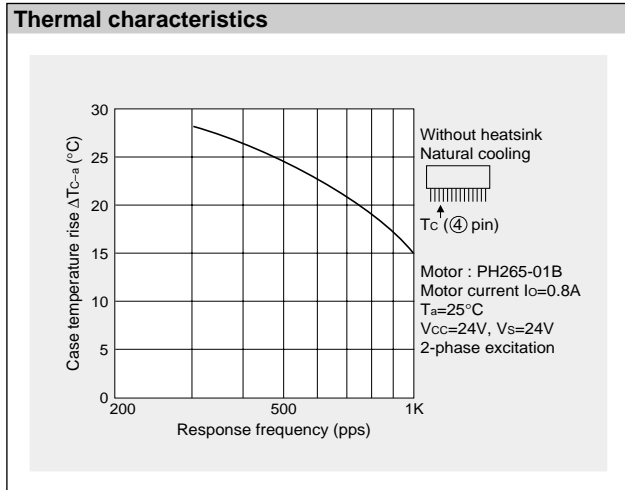

- (2) The power dissipation  $P_{diss}$  is obtained using the following formula.

2-phase excitation:  $P_{diss} \cong 2P_H + 0.015 \times V_s$  (W)

1-2 phase excitation:  $P_{diss} \cong \frac{3}{2} P_H + 0.015 \times V_s$  (W)

- (3) Obtain the temperature rise that corresponds to the calculated value of  $P_{diss}$  from Fig. 7 "Temperature rise."

■Handling Precautions

The input terminals of this product use C-MOS circuits. Observe the following precautions.

- Carefully control the humidity of the room to prevent the buildup of static electricity. Since static electricity is particularly a problem during the winter, be sure to take sufficient precautions.
- Take care to make sure that static electricity is not applied to the IC during wiring and assembly. Take precautions such as shorting the terminals of the printed wiring board to ensure that they are at the same electrical potential.

## Determining the Output Current

Fig. 1 shows the waveform of the output current (motor coil current). The method of determining the peak value of the output current ( $I_o$ ) based on this waveform is shown below.

(Parameters for determining the output current  $I_o$ )

$V_b$ : Reference supply voltage

$r_1, r_2$ : Voltage-divider resistors for the reference supply voltage

$R_s$ : Current sense resistor

(1) Normal rotation mode

$I_o$  is determined as follows when current flows at the maximum level during motor rotation. (See Fig.2.)

$$I_o \cong \frac{r_2}{r_1+r_2} \cdot \frac{V_b}{R_s} \dots\dots\dots (1)$$

(2) Power down mode

The circuit in Fig.3 ( $r_x$  and  $T_r$ ) is added in order to decrease the coil current.  $I_o$  is then determined as follows.

$$I_{OPD} \cong \frac{1}{1 + \frac{r_1(r_2+r_x)}{r_2 \cdot r_x}} \cdot \frac{V_b}{R_s} \dots\dots\dots (2)$$

Equation (2) can be modified to obtain equation to determine  $r_x$ .

$$r_x = \frac{1}{\frac{1}{r_1} \left( \frac{V_b}{R_s \cdot I_{OPD}} - 1 \right) - \frac{1}{r_2}}$$

Fig. 4 and 5 show the graphs of equations (1) and (2) respectively.

Fig. 1 Waveform of coil current (Phase A excitation ON)

Fig. 2 Normal mode

Fig. 3 Power down mode

Fig. 4 Output current  $I_o$  vs. Current sense resistor  $R_s$

Fig. 5 Output current  $I_{OPD}$  vs. Variable current sense resistor  $r_x$

**(NOTE)**

Ringing noise is produced in the current sense resistor  $R_s$  when the MOSFET is switched ON and OFF by chopping. This noise is also generated in feedback signals from  $R_s$  which may therefore cause the comparator to malfunction. To prevent chopping malfunctions,  $r_5(r_6)$  and  $C_3(C_4)$  are added to act as a noise filter.

However, when the values of these constants are increased, the response from  $R_s$  to the comparator becomes slow. Hence the value of the output current  $I_o$  is somewhat higher than the calculated value.

**Determining the chopper frequency**

Determining  $T_{OFF}$

The SLA7000M series are self-excited choppers. The chopping OFF time  $T_{OFF}$  is fixed by  $r_3/C_1$  and  $r_4/C_2$  connected to terminal Td.

$T_{OFF}$  can be calculated using the following formula:

$$T_{OFF} \approx -r_3 \cdot C_1 \ln \left(1 - \frac{2}{V_b}\right) = -r_4 \cdot C_2 \ln \left(1 - \frac{2}{V_b}\right)$$

The circuit constants and the  $T_{OFF}$  value shown below are recommended.

$T_{OFF} = 12\mu s$  at  $r_3=47k\Omega$ ,  $C_1=500pF$ ,  $V_b=5V$

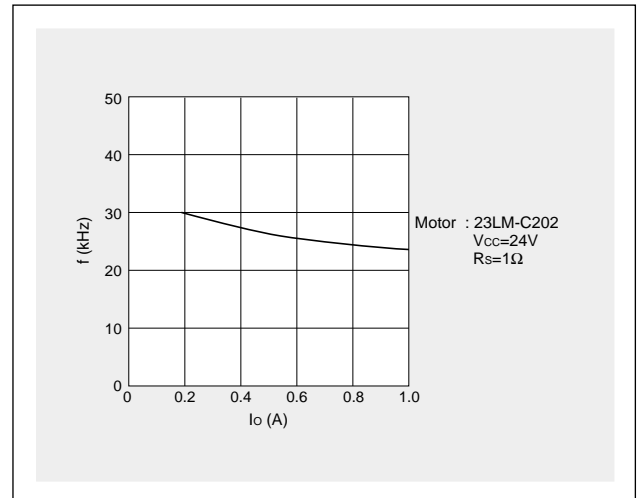

**Fig. 6 Chopper frequency vs. Motor coil resistance**

**Chopper frequency vs. Supply voltage**

**Chopper frequency vs. Output current**

**Thermal Design**

An outline of the method for calculating heat dissipation is shown below.

(1) Obtain the value of  $P_H$  that corresponds to the motor coil current  $I_o$  from Fig. 7 "Heat dissipation per phase  $P_H$  vs. Output current  $I_o$ ."

(2) The power dissipation  $P_{diss}$  is obtained using the following formula.

2-phase excitation:  $P_{diss} \cong 2P_H + 0.015 \times V_s$  (W)

1-2 phase excitation:  $P_{diss} \cong \frac{3}{2} P_H + 0.015 \times V_s$  (W)

(3) Obtain the temperature rise that corresponds to the calculated value of  $P_{diss}$  from Fig. 8 "Temperature rise."

## Outline

SLA7032M (SLA7033M) is a stepper motor driver IC developed to reduce the number of external parts required by the conventional SLA7024M (SLA7026M). This IC successfully eliminates the need for some external parts without sacrificing the features of SLA7024M (SLA7026M). The basic function pins are compatible with those of SLA7024M (SLA7026M).

## Notes on Replacing SLA7024M (SLA7026M)

SLA7032M (SLA7033M) is pin-compatible with SLA7024M (SLA7026M). When using the IC on an existing board, the following preparations are necessary:

- (1) Remove the resistors and capacitors attached for setting the chopping OFF time. ( $r_3$ ,  $r_4$ ,  $C_1$ , and  $C_2$  in the catalog)
- (2) Remove the resistors and capacitors attached for preventing noise in the detection voltage  $V_{RS}$  from causing malfunctioning and short the sections from which the resistors were removed using jumper wires. ( $r_5$ ,  $r_6$ ,  $C_3$ , and  $C_4$  in the catalog)
- (3) Normally, keep pins 2 and 13 grounded because their functions have changed to synchronous and asynchronous switching (SYNC terminals). For details, see "Circuit for Preventing Abnormal Noise When the Motor Is Not Running (Synchronous circuit)." (Low: asynchronous, High: synchronous)

## Circuit for Preventing Abnormal Noise When the Motor Is Not Running (Synchronous Circuit)

A motor may generate abnormal noise when it is not running. This phenomenon is attributable to asynchronous chopping between phases A and B. To prevent the phenomenon, SLA7032M (SLA7033M) contains a synchronous chopping circuit. Do not leave

the SYNC terminals open because they are for CMOS input. Connect TTL or similar to the SYNC terminals and switch the SYNC terminal level high or low.

When the motor is not running, set the TTL signal high (SYNC terminal voltage: 4 V or more) to make chopping synchronous. When the motor is running, set the TTL signal low (SYNC terminal voltage: 0.8 V or less) to make chopping asynchronous. If chopping is set to synchronous at when the motor is running, the motor torque deteriorates before the coil current reaches the set value. If no abnormal noise occurs when the motor is not running, ground the SYNC terminals (TTL not necessary).

The built-in synchronous chopping circuit superimposes a trigger signal on the REF terminal for synchronization between the two phases. The figure below shows the internal circuit of the REF terminal. Since the  $\Delta V_{REF}$  varies depending on the values of R1 and R2, determine these values for when the motor is not running within the range where the two phases are synchronized.

**Determining the Output Current**

Fig. 1 shows the waveform of the output current (motor coil current). The method of determining the peak value of the output current (Io) based on this waveform is shown below.

(Parameters for determining the output current Io)

- Vb: Reference supply voltage
- r1,r2: Voltage-divider resistors for the reference supply voltage
- Rs: Current sense resistor

(1) Normal rotation mode

Io is determined as follows when current flows at the maximum level during motor rotation. (See Fig.2.)

$$I_o \cong \frac{r_2}{r_1+r_2} \cdot \frac{V_b}{R_s} \dots\dots\dots (1)$$

(2) Power down mode

The circuit in Fig.3 (rx and Tr) is added in order to decrease the coil current. Io is then determined as follows.

$$I_{OPD} \cong \frac{1}{1 + \frac{r_1(r_2+r_x)}{r_2 \cdot r_x}} \cdot \frac{V_b}{R_s} \dots\dots\dots (2)$$

Equation (2) can be modified to obtain equation to determine rx.

$$r_x = \frac{1}{\frac{1}{r_1} \left( \frac{V_b}{R_s \cdot I_{OPD}} - 1 \right) - \frac{1}{r_2}}$$

Fig. 4 and 5 show the graphs of equations (1) and (2) respectively.

**Thermal Design**

An outline of the method for calculated heat dissipation is shown below.

(1) Obtain the value of  $P_H$  that corresponds to the motor coil current  $I_o$  from Fig. 6 "Heat dissipation per phase  $P_H$  vs. Output current  $I_o$ ."

(2) The power dissipation  $P_{diss}$  is obtained using the following formula.

2-phase excitation:  $P_{diss} \cong 2P_H + 0.015 \times V_s$  (W)

1-2 phase excitation:  $P_{diss} \cong \frac{3}{2} P_H + 0.015 \times V_s$  (W)

(3) Obtain the temperature rise that corresponds to the computed value of  $P_{diss}$  from Fig. 7 "Temperature rise."

# Application Notes

## Determining the Output Current

Fig. 1 shows the waveform of the output current (motor coil current). The method of determining the peak value of the output current ( $I_o$ ) based on this waveform is shown below.

(Parameters for determining the output current  $I_o$ )

- $V_b$ : Reference supply voltage
- $r_1, r_2$ : Voltage-divider resistors for the reference supply voltage
- $R_s$ : Current sense resistor

### (1) Normal rotation mode

$I_o$  is determined as follows when current flows at the maximum level during motor rotation. (See Fig.2.)

$$I_o \cong \frac{r_2}{r_1+r_2} \cdot \frac{V_b}{R_s} \dots\dots\dots (1)$$

### (2) Power down mode

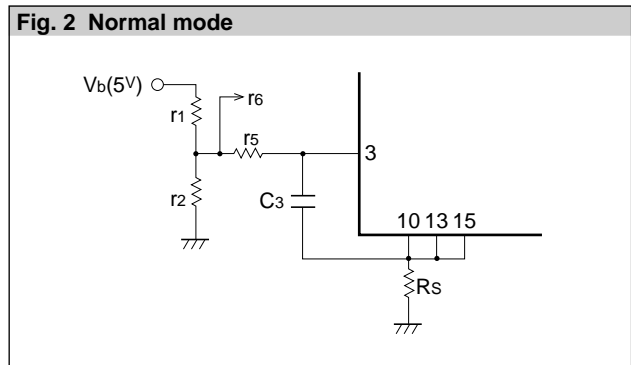

The circuit in Fig.3 ( $r_x$  and  $T_r$ ) is added in order to decrease the coil current.  $I_o$  is then determined as follows.

$$I_{OPD} \cong \frac{1}{1 + \frac{r_1(r_2+r_x)}{r_2 \cdot r_x}} \cdot \frac{V_b}{R_s} \dots\dots\dots (2)$$

Equation (2) can be modified to obtain equation to determine  $r_x$ .

$$r_x = \frac{1}{\frac{1}{r_1} \left( \frac{V_b}{R_s \cdot I_{OPD}} - 1 \right) - \frac{1}{r_2}}$$

Fig. 4 and 5 show the graphs of equations (1) and (2) respectively.

**(NOTE)**

Ringing noise is produced in the current sense resistor  $R_s$  when the MOSFET is switched ON and OFF by chopping. This noise is also generated in feedback signals from  $R_s$  which may therefore cause the comparator to malfunction. To prevent chopping malfunctions,  $r_5(r_6)$  and  $C_3(C_4)$  are added to act as a noise filter.

However, when the values of these constants are increased, the response from  $R_s$  to the comparator becomes slow. Hence the value of the output current  $I_o$  is somewhat higher than the calculated value.

**Determining the chopper frequency**

Determining  $T_{OFF}$

SDK03M is self-excited choppers. The chopping OFF time  $T_{OFF}$  is fixed by  $r_3/C_1$  and  $r_4/C_2$  connected to terminal  $T_d$ .

$T_{OFF}$  can be calculated using the following formula:

$$T_{OFF} \approx -r_3 \cdot C_1 \ln\left(1 - \frac{2}{V_b}\right) = -r_4 \cdot C_2 \ln\left(1 - \frac{2}{V_b}\right)$$

The circuit constants and the  $T_{OFF}$  value shown below are recommended.

$$T_{OFF} = 12\mu s \text{ at } r_3=47k\Omega, C_1=500pF, V_b=5V$$

**Fig. 6 Chopper frequency vs. Motor coil resistance**

**Chopper frequency vs. Supply voltage**

**Chopper frequency vs. Output current**

**Thermal Design**

An outline of the method for computing heat dissipation is shown below.

- (1) Obtain the value of  $P_H$  that corresponds to the motor coil current  $I_o$  from Fig. 7 "Heat dissipation per phase  $P_H$  vs. Output current  $I_o$ ."

- (2) The power dissipation  $P_{diss}$  is obtained using the following formula.  
 2-phase excitation:  $P_{diss} \cong P_H + 0.0075 \times V_s$  (W)  
 1-2 phase excitation:  $P_{diss} \cong \frac{3}{4} P_H + 0.0075 \times V_s$  (W)
- (3) Obtain the temperature rise that corresponds to the calculated value of  $P_{diss}$  from Fig. 8 "Temperature rise."

**Supply Voltage Vcc vs. Supply Current Icc**

**Torque Characteristics**

**Note**

The excitation input signals of the SDK03M can be used as either Active High or Active Low. Note, However, that the corresponding output (OUT) changes depending on the input (IN).

**Active High**

Input	Corresponding output
IN <sub>1</sub> (pin6)	OUT <sub>1</sub> (pin1, 16)
IN <sub>2</sub> (pin5)	OUT <sub>2</sub> (pin8, 9)

**Active Low**

Input	Corresponding output
IN <sub>1</sub> (pin6)	OUT <sub>1</sub> (pin8, 9)
IN <sub>2</sub> (pin5)	OUT <sub>2</sub> (pin1, 16)

# 2-Phase Stepper Motor Unipolar Driver IC

Allegro MicroSystems product

## Features

- Internal 1-phase/1-2 phase/2-phase excitation pattern generator
- Output enable and direction control
- Power-on reset
- Internal thermal shutdown circuitry
- Internal transient-suppression diodes
- Low thermal resistance 16-pin DIP

## Absolute Maximum Ratings

( $T_a=+25^\circ\text{C}$ )

Parameter	Symbol	Ratings	Units
Output voltage	$V_{CE}$	50	V
Output sustaining voltage	$V_{CE(SUS)}$	35	V
Output current (1 circuit)	$I_o$	1.5	A/unit
Logic supply voltage	$V_{DD}$	7.0	V
Input voltage	$V_{IN}$	7.0	V
Package power dissipation	$P_D$ (Note1)	2.90	W/pkg
Operating temperature	$T_a$	-20 to +85	$^\circ\text{C}$
Junction temperature	$T_j$ (Note2)	+150	$^\circ\text{C}$
Storage temperature	$T_{stg}$	-55 to +150	$^\circ\text{C}$

Note 1: When ambient temperature is  $25^\circ\text{C}$  or over, derate using  $-23.3\text{mW}/^\circ\text{C}$ .

Note 2: Fault conditions where junction temperature ( $T_j$ ) exceeds  $150^\circ\text{C}$  will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

## Electrical Characteristics

(Unless specified otherwise,  $T_a=25^\circ\text{C}$ ,  $V_{DD}=4.5\text{V}$  to  $5.5\text{V}$ )

Parameter	Symbol	Conditions	Limits			Units
			min	typ	max	
Output drivers						
Output leakage current	$I_{CEX}$	$V_o=50\text{V}$		10	50	$\mu\text{A}$
Output sustaining voltage	$V_{CE(SUS)}$	$I_o=1.25\text{A}$ , $L=3\text{mH}$	3.5			V
Output saturation voltage	$V_{CE(SAT)}$	$I_o=700\text{mA}$		1.0	1.2	V
		$I_o=1\text{A}$		1.1	1.4	V
		$I_o=1.25\text{A}$		1.2	1.5	V
Clamp diode leakage current	$I_R$	$V_R=50\text{V}$		10	50	$\mu\text{A}$
Clamp diode forward voltage	$V_F$	$I_F=1.25\text{A}$		1.5	3.0	V
Turn-on delay	$t_{ON}$	50% step inputs to 50% output			10	$\mu\text{s}$
Turn-off delay	$t_{OFF}$	50% step inputs to 50% output			10	$\mu\text{s}$
Thermal shutdown temperature	$T_j$			165		$^\circ\text{C}$
Control logic						
(Unless specified otherwise, $V_{IN}=V_{DD}$ or GND)						
Input current	$I_{IH}$	$V_{IN}=V_{DD}$		0.5	5.0	$\mu\text{A}$
	$I_{IL}$	$V_{IN}=0.8\text{V}$		-0.5	-5.0	$\mu\text{A}$
Input voltage	$V_{IH}$	$V_{DD}=5\text{V}$	3.5		5.3	V
	$V_{IL}$		-0.3		0.8	V
Supply current	$I_{DD}$	2 outputs ON		20	30	mA
Data setup time	$t_{S(DAT(A))}$	Inter-clock	100			ns
Data hold time	$t_{H(DAT(B))}$	Inter-clock	100			ns
Clock pulse width	$t_w(\text{CLK(C)})$		500			ns

● "typ" values are for reference.

	MODE4 (71.4%)	0	0
	MODE5 (83%)	0	0
	MODE6 (91%)	0	0
	MODE7 (100%)	0	0

See page 48 for details of PG001M serial signal generator IC for SLA7042M and SLA7044M.

Successively output this serial data and set any current. Then, determine the step time of the reference voltage  $V_{ref}$  at  $\overline{\text{STROBE}}$  signal intervals.

**Current Vector Locus (One step of stepper motor normalized to 90 degrees)**

**Serial Data Sequence Example (2W 1-2 Phase Excitation for CW)**

Sequence	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	0
DATA-A MODE	4	3	2	1	0	$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{6}$	$\bar{7}$	$\bar{7}$	$\bar{6}$	$\bar{5}$	$\bar{4}$	$\bar{3}$	$\bar{2}$	$\bar{1}$	$\bar{0}$	1	2	3	4	5	6	7	7	7	6	5	4	
DATA-B MODE	4	5	6	7	7	7	6	5	4	3	2	1	0	$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{6}$	$\bar{7}$	$\bar{7}$	$\bar{6}$	$\bar{5}$	$\bar{4}$	$\bar{3}$	$\bar{2}$	$\bar{1}$	0	1	2	3	4	

A malfunction may occur just after the power ( $V_{DD}$ ) is turned on because the internal logic is unstable. Therefore, set the RESET state (REF terminal voltage:  $V_{DD}-1V$  to  $V_{DD}$ ) after the power is turned on.)

**Operation Current Waveform Examples**

These three types of waveforms can all be set with a serial signal.

For 2-2 phase VC:L, output mode is 7→4.

# 2-Phase Stepper Motor Bipolar Driver IC

Allegro MicroSystems product

## ■ Features

- Maximum output ratings: 30V, ±650mA
- Internal fixed-frequency PWM current control
- Internal ground-clamp & flyback diodes
- Internal thermal shutdown, crossover-current protection and UVLO protection circuitry
- Employs copper batwing lead frame with low thermal resistance

## ■ Absolute Maximum Ratings

Parameter	Symbol	Ratings		Units
		A3966SA	A3966SLB	
Load supply voltage	$V_{BB}$	30		V
Output current (peak)	$I_o$ (Peak)	±750		mA
Output current (continuous)	$I_o$	±650		mA
Logic supply voltage	$V_{CC}$	7.0		V
Logic input voltage range	$V_{IN}$	-0.3 to $V_{CC}+0.3$		V
Sense voltage	$V_s$	1.0		V
Package power dissipation	$P_D$ (Note1)	2.08	1.86	W
Ambient operating temperature	$T_a$	-20 to +85		°C
Junction temperature	$T_j$ (Note2)	+150		°C
Storage temperature	$T_{stg}$	-55 to +150		°C

● Output current rating may be limited by duty cycle, ambient temperature, and heat sinking. Under any set of conditions, do not exceed the specified current rating or a junction temperature of 150°C.

Note 1: When ambient temperature is 25°C or over, derate using -16.67mW/°C (SA), -14.93mW/°C (SLB).

Note 2: Fault conditions where junction temperature ( $T_j$ ) exceeds 150°C will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

## ■ Electrical Characteristics (Unless specified otherwise, $T_a=25^\circ\text{C}$ , $V_{BB}=30\text{V}$ , $V_{CC}=4.75\text{V}$ to 5.5V, $V_{REF}=2\text{V}$ , $V_s=0\text{V}$ , 56kΩ & 680pF RC to ground)

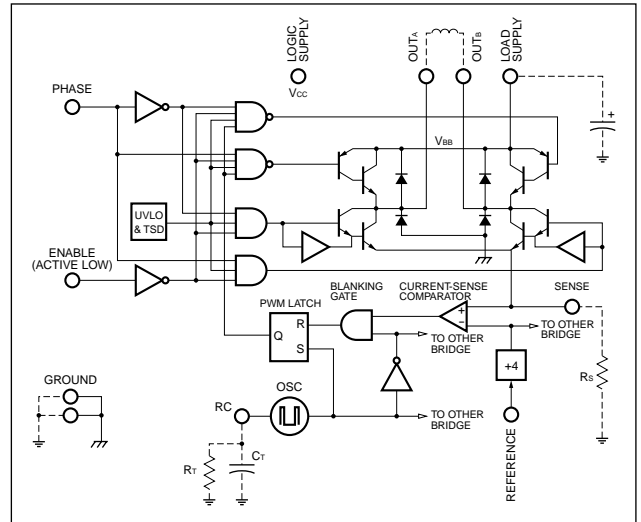

Parameter	Symbol	Conditions	Ratings			Units

# 2-Phase Stepper Motor Bipolar Driver IC

Allegro MicroSystems product

## Features

- Fixed off-time PWM current control
- Internally generated, precision 2.5V reference
- External filter for sense terminal not required
- Internal thermal shutdown circuitry
- Internal crossover-current protection circuitry
- Internal UVLO protection
- Internal transient-suppression diodes
- Low thermal resistance 20-pin SOP

## Absolute Maximum Ratings

Parameter	Symbol	Ratings	Units
Load supply voltage	V <sub>BB</sub>	30	V
Output current (continuous)	I <sub>O</sub>	±0.80	A
Logic supply voltage	V <sub>CC</sub>	7.0	V
Logic input voltage range	V <sub>IN</sub>	-0.3 to V <sub>CC</sub> +0.3	V

# 2-Phase Stepper Motor Bipolar Driver ICs

Allegro MicroSystems product

## ■ Features

- Fixed off-time PWM current control
- Switching between power supply regeneration mode and loop regeneration mode in order to improve motor current response in microstepping
- External filter for sense terminal not required
- 3.3V and 5V logic supply voltage
- Sleep (low current consumption) mode
- Brake operation with PWM current limiting
- Internal thermal shutdown circuitry
- Internal crossover-current protection circuitry
- Internal UVLO protection
- Internal transient-suppression diodes
- Low thermal resistance package

## ■ Absolute Maximum Ratings

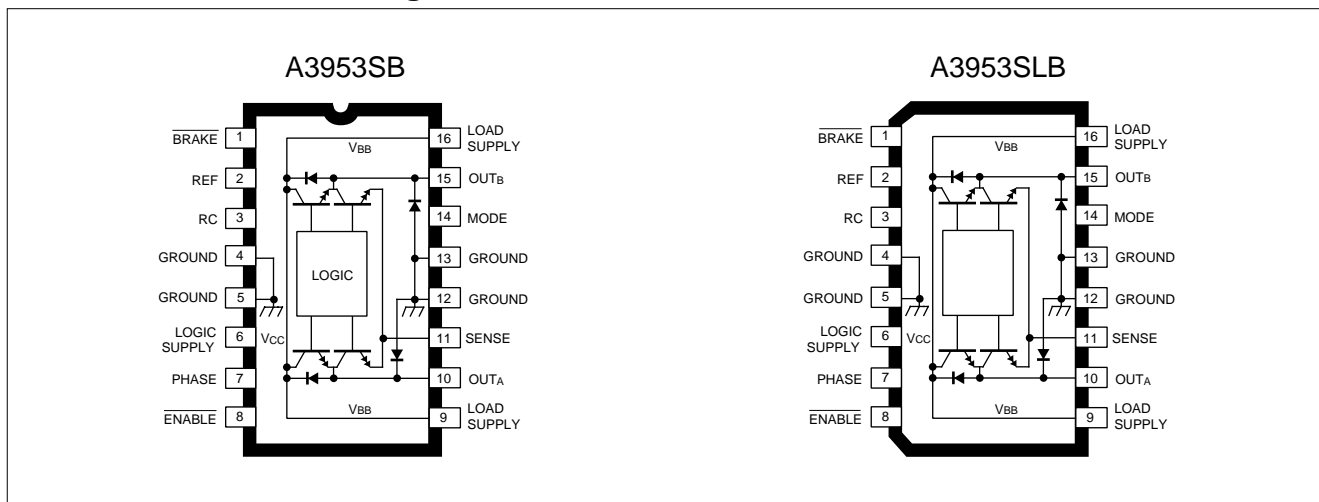

Parameter	Symbol	Ratings		Units
		A3953SB	A3953SLB	
Load supply voltage	$V_{BB}$	50		V
Output current (continuous)	$I_o$	$\pm 1.3$		A/unit
Logic supply voltage	$V_{CC}$	7.0		V
Logic/reference input voltage range	$V_{IN}$	$-0.3$ to $V_{CC}+0.3$		V
Sense voltage	$V_{SENSE}$ D.C.	1.0 ( $V_{CC}=5.0V$ )		V
		0.4 ( $V_{CC}=3.3V$ )		
Package power dissipation	$P_D$ (Note1)	2.90	1.86	W/pkg
Operating temperature	$T_a$	$-20$ to $+85$		$^{\circ}C$
Junction temperature	$T_j$ (Note2)	$+150$		$^{\circ}C$
Storage temperature	$T_{stg}$	$-55$ to $+150$		$^{\circ}C$

● Output current rating may be limited by duty cycle, ambient temperature, and heat sinking. Under any set of conditions, do not exceed the specified current rating or a junction temperature of 150°C.

Note 1: When ambient temperature is 25°C or over, derate using  $-23.26mW/^{\circ}C$ (SB) or  $-14.93mW/^{\circ}C$ (SLB).

Note 2: Fault conditions where junction temperature ( $T_j$ ) exceeds 150°C will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

Application Circuit

Off-time setting  
 $t_{OFF} = R_T \cdot C_T$   
 $R_T = 12k$  to  $100k\Omega$   
 $C_T = 470$  to  $1500pF$  (Operating at  $V_{CC} = 5V$ )  
 $C_T = 680$  to  $1500pF$  (Operating at  $V_{CC} = 3.3V$ )

External Dimensions

(Unit: mm)

- Thickness of lead is measured below seating plane.
- Allowable variation in distance between leads is not cumulative.
- Note 1: Lead width of pin 1, 8, 9, 16 may be 2: half the value shown here.
- Maximum thickness of lead is 0.508mm.

- Pin material: copper, pin surface treatment: solder plating
- Package index may be \*1.
- Allowable variation in distance between leads is not cumulative.
- Web (batwing) type lead frames are used for pin 4, 5, 12, 13. The pins are connected to GND.

## Application Notes

### ■Outline

Designed for bidirectional pulse-width modulated (PWM) current control of inductive loads, the A3953S- is capable of continuous output currents to  $\pm 1.3\text{A}$  and operating voltages to 50V. Internal fixed off-time PWM current-control circuitry can be used to regulate the maximum load current to a desired value. The peak load current limit is set by the user's selection of an input reference voltage and external sensing resistor. The fixed off-time pulse duration is set by a userselected external RC timing network. Internal circuit protection includes thermal shutdown with hysteresis, transient-suppression diodes, and crossover current protection. Special power-up sequencing is not required. With the ENABLE input held low, the PHASE input controls load current polarity by selecting the appropriate source and sink driver pair. The MODE input determines whether the PWM current-control circuitry operates in a slow current-decay mode (only the selected source driver switching) or in a fast current-decay mode (selected source and sink switching). A user-selectable blanking window prevents false triggering of the PWM current-control circuitry. With the ENABLE input held high, all output drivers are disabled. A sleep mode is provided to reduce power consumption.

When a logic low is applied to the Brake input, the braking function is enabled. This overrides ENABLE and PHASE to turn OFF both source drivers and turn ON both sink drivers. The brake function can be used to dynamically brake brush dc motors.

### ■FUNCTIONAL DESCRIPTION

#### (A) Internal PWM Current Control During Forward and Reverse Operation.

The A3953S-contains a fixed off-time pulse-width modulated (PWM) current-control circuit that can be used to limit the load current to a desired value. The peak value of the current limiting ( $I_{TRIP}$ ) is set by the selection of an external current sensing resistor ( $R_s$ ) and reference input voltage ( $V_{REF}$ ). The internal circuitry compares the voltage across the external sense resistor to the voltage on the reference input terminal (REF) resulting in a transconductance function approximated by:

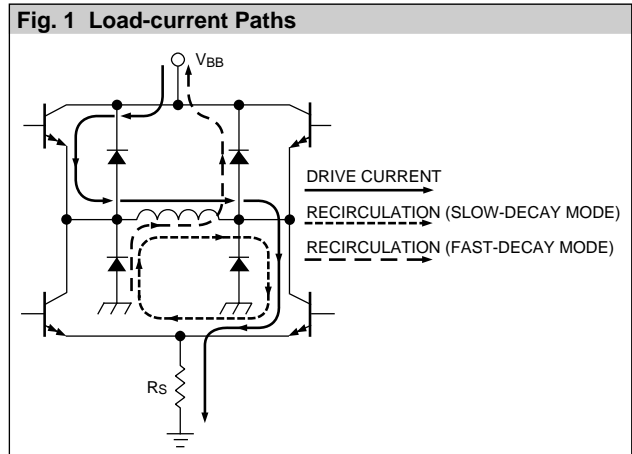

$$I_{TRIP} \approx \frac{V_{REF}}{R_{SENSE}} - I_{SO}$$

where  $I_{SO}$  is the offset due to base drive current.

In forward or reverse mode the current-control circuitry limits the load current as follows: when the load current reaches  $I_{TRIP}$ , the comparator resets a latch that turns off the selected source driver or selected sink and source driver pair depending on whether the device is operating in slow or fast current-decay mode, respectively.

In slow current-decay mode, the selected source driver is disabled; the load inductance causes the current to recirculate through the sink driver and ground clamp diode. In fast current-

decay mode, the selected sink and source driver pair are disabled; the load inductance causes the current to flow from ground to the load supply via the ground clamp and flyback diodes.

The user selects an external resistor ( $R_T$ ) and capacitor ( $C_T$ ) to determine the time period ( $t_{OFF}=R_T \cdot C_T$ ) during which the drivers remain disabled (see "RC Fixed Off-time" below). At the end of the RC interval, the drivers are enabled allowing the load current to increase again. The PWM cycle repeats, maintaining the peak load current at the desired value (see figure 2).

#### (B) INTERNAL PWM CURRENT CONTROL DURING BRAKE-MODE OPERATION

##### (1) Brake Operation-MODE Input High.

The brake circuit turns OFF both source drivers and turns ON both sink drivers. For dc motor applications, this has the effect of shoring the motor's back-EMF voltage resulting in current flow that dynamically brakes the motor. If the back-EMF voltage is large, and there is no PWM current limiting, the load current can increase to a value that approaches that of a locked rotor condition. To limit the current, when the  $I_{TRIP}$  level is reached, the PWM circuit disables the conducting sink drivers. The energy stored in the motor's inductance is discharged into the load supply causing the motor current to decay.

As in the case of forward/reverse operation, the drivers are enabled after a time given by  $t_{OFF}=R_T \cdot C_T$  (see "RC Fixed Off-time" below). Depending on the back-EMF voltage (proportional to the motor's decreasing speed), the load current again may in-

crease to  $I_{TRIP}$ . If so, the PWM cycle will repeat, limiting the peak load current to the desired value.

During braking, when the MODE input is high, the peak current limit can be approximated by:

$$I_{TRIP\ BRAKE\ MH} \approx \frac{V_{REF}}{R_{SENSE}}$$

**CAUTION:** Because the kinetic energy stored in the motor and load inertia is being converted into current, which charges the  $V_{BB}$  supply bulk capacitance (power supply output and decoupling capacitance), care must be taken to ensure the capacitance is sufficient to absorb the energy without exceeding the voltage rating of any devices connected to the motor supply.

### (2) Brake Operation-MODE Input Low.

During braking, with the MODE input low, the internal current-control circuitry is disabled. Therefore, care should be taken to ensure that the motor's current does not exceed the ratings of the device. The braking current can be measured by using an oscilloscope with a current probe connected to one of the motor's leads, or if the back-EMF voltage of the motor is known, approximated by:

$$I_{PEAK\ BRAKE\ ML} \approx \frac{V_{BEMF}-1V}{R_{LOAD}}$$

### (C) RC Fixed Off-Time.

The internal PWM current-control circuitry uses a one shot to control the time the driver (s) remain (s) off. The one-shot time,  $t_{OFF}$  (fixed off-time), is determined by the selection of an external resistor ( $R_T$ ) and capacitor ( $C_T$ ) connected in parallel from the RC timing terminal to ground. The fixed off-time, over a range of values of  $C_T=470pF$  to  $1500pF$  and  $R_T=12k\Omega$  to  $100k\Omega$ , is approximated by:

$$t_{off} \approx R_T \cdot C_T$$

The operation of the circuit is as follows: when the PWM latch is reset by the current comparator, the voltage on the RC terminal will begin to decay from approximately  $0.60V_{CC}$ . When the voltage on the RC terminal reaches approximately  $0.22V_{CC}$ , the PWM latch is set, thereby enabling the driver (s).

### (D) RC Blanking.

In addition to determining the fixed off-time of the PWM control circuit, the  $C_T$  component sets the comparator blanking time. This function blanks the output of the comparator when the outputs are switched by the internal current-control circuitry (or by the PHASE, BRAKE, or ENABLE inputs). The comparator output is blanked to prevent false over-current detections due to reverse recovery currents of the clamp diodes, and/or switching transients related to distributed capacitance in the load.

During internal PWM operation, at the end of the  $t_{OFF}$  time, the

comparator's output is blanked and  $C_T$  begins to be charged from approximately  $0.22V_{CC}$  by an internal current source of approximately 1 mA. The comparator output remains blanked until the voltage on  $C_T$  reaches approximately  $0.60V_{CC}$ .

When a transition of the PHASE input occurs,  $C_T$  is discharged to near ground during the crossover delay time (the crossover delay time is present to prevent simultaneous conduction of the source and sink drivers). After the crossover delay,  $C_T$  is charged by an internal current source of approximately 1 mA. The comparator output remains blanked until the voltage on  $C_T$  reaches approximately  $0.60V_{CC}$ .

When the device is disabled, via the ENABLE input,  $C_T$  is discharged to near ground. When the device is reenabled,  $C_T$  is charged by an internal current source of approximately 1 mA. The comparator output remains blanked until the voltage on  $C_T$  reaches approximately  $0.60V_{CC}$ .

For 3.3 V operation,

the minimum recommended value for  $C_T$  is  $680pF \pm 5\%$ .

For 5.0V operation,

the minimum recommended value for  $C_T$  is  $470pF \pm 5\%$ .

These values ensure that the blanking time is sufficient to avoid false trips of the comparator under normal operating conditions.

For optimal regulation of the load current, the above values for  $C_T$  are recommended and the value of  $R_T$  can be sized to determine  $t_{OFF}$ . For more information regarding load current regulation, see below.

### (E) LOAD CURRENT REGULATION WITH INTERNAL PWM CURRENT-CONTROL CIRCUITRY

When the device is operating in slow current-decay mode, there is a limit to the lowest level that the PWM current-control circuitry can regulate load current. The limitation is the minimum duty cycle, which is a function of the user-selected value of  $t_{OFF}$  and the minimum on-time pulse  $t_{ON(min)max}$  that occurs each time the PWM latch is reset. If the motor is not rotating (as in the case of a stepper motor in hold/detent mode, a brush dc motor when stalled, or at startup), the worst case value of current regulation can be approximated by:

$$I_{AVE} \equiv \frac{[(V_{BB}-V_{SAT(source+sink)}) \cdot t_{ON(min)max}] - [1.05 \cdot (V_{SAT(sink)} + V_F) \cdot t_{off}]}{1.05 \cdot (t_{ON(min)max} + t_{off}) \cdot R_{LOAD}}$$

where  $t_{OFF}=R_T \cdot C_T$ ,  $R_{LOAD}$  is the series resistance of the load,  $V_{BB}$  is the motor supply voltage and  $t_{ON(min)max}$  is specified in the electrical characteristics table. When the motor is rotating, the back EMF generated will influence the above relationship. For brush dc motor applications, the current regulation is improved. For stepper motor applications, when the motor is rotating, the effect is more complex. A discussion of this subject is included in the section on stepper motors below.

The following procedure can be used to evaluate the worst-case slow current-decay internal PWM load current regulation in the system:

Set  $V_{REF}$  to 0 volts. With the load connected and the PWM current control operating in slow current-decay mode, use an oscilloscope to measure the time the output is low (sink ON) for the output that is chopping. This is the typical minimum ON time ( $t_{ON(min)}$  typ) for the device.

The  $C_T$  then should be increased until the measured value of  $t_{ON(min)}$  is equal to  $t_{ON(min)}$  max as specified in the electrical characteristics table. When the new value of  $C_T$  has been set, the value of  $R_T$  should be decreased so the value for  $t_{OFF} = R_T \cdot C_T$  (with the artificially increased value of  $C_T$ ) is equal to the nominal design value. The worst-case load-current regulation then can be measured in the system under operating conditions.

#### (F) PWM of the PHASE and ENABLE Inputs.

The PHASE and ENABLE inputs can be pulse-width modulated to regulate load current. Typical propagation delays from the PHASE and ENABLE inputs to transitions of the power outputs are specified in the electrical characteristics table. If the internal PWM current control is used, the comparator blanking function is active during phase and enable transitions. This eliminates false tripping of the over-current comparator caused by switching transients (see “RC Blanking” above).

##### (1) Enable PWM.

With the MODE input low, toggling the ENABLE input turns ON and OFF the selected source and sink drivers. The corresponding pair of flyback and ground-clamp diodes conduct after the drivers are disabled, resulting in fast current decay. When the device is enabled the internal current-control circuitry will be active and can be used to limit the load current in a slow current-decay mode.

For applications that PWM the ENABLE input and desire the internal current-limiting circuit to function in the fast decay mode, the ENABLE input signal should be inverted and connected to the MODE input. This prevents the device from being switched into sleep mode when the ENABLE input is low.

##### (2) Phase PWM.

Toggling the PHASE terminal selects which sink/source pair is enabled, producing a load current that varies with the duty cycle and remains continuous at all times. This can have added benefits in bidirectional brush dc servo motor applications as the transfer function between the duty cycle on the PHASE input and the average voltage applied to the motor is more linear than in the case of ENABLE PWM control (which produces a discontinuous current at low current levels). For more information see “DC Motor Applications” below.

##### (3) Synchronous Fixed-Frequency PWM.

The internal PWM current-control circuitry of multiple A3953S-devices can be synchronized by using the simple circuit shown in figure 3. A 555IC can be used to generate the reset pulse/blanking signal ( $t_1$ ) for the device and the period of the PWM cycle ( $t_2$ ). The value of  $t_1$  should be a minimum of 1.5ms. When used in this configuration, the  $R_T$  and  $C_T$  components should be

omitted. The PHASE and ENABLE inputs should not be PWM with this circuit configuration due to the absence of a blanking function synchronous with their transitions.

#### (G) Miscellaneous Information.

A logic high applied to both the ENABLE and MODE terminals puts the device into a sleep mode to minimize current consumption when not in use.

An internally generated dead time prevents crossover currents that can occur when switching phase or braking.

Thermal protection circuitry turns OFF all drivers should the junction temperature reach 165°C (typical). This is intended only to protect the device from failures due to excessive junction temperatures and should not imply that output short circuits are permitted. The hysteresis of the thermal shutdown circuit is approximately 8°C.

## APPLICATION NOTES

#### (A) Current Sensing.

The actual peak load current ( $I_{PEAK}$ ) will be above the calculated value of  $I_{TRIP}$  due to delays in the turn off of the drivers. The amount of overshoot can be approximated by:

$$I_{OS} \approx \frac{(V_{BB} - [(I_{TRIP} \cdot R_{LOAD}) + V_{BEMF}]) \cdot t_{PWM(OFF)}}{L_{LOAD}}$$

where  $V_{BB}$  is the motor supply voltage,  $V_{BEMF}$  is the back-EMF voltage of the load,  $R_{LOAD}$  and  $L_{LOAD}$  are the resistance and inductance of the load respectively, and  $t_{PWM(OFF)}$  is specified in the electrical characteristics table.

The reference terminal has a maximum input bias current of  $\pm 5\mu A$ . This current should be taken into account when determining the impedance of the external circuit that sets the reference voltage value.

To minimize current-sensing inaccuracies caused by ground trace  $I \cdot R$  drops, the current-sensing resistor should have a separate return to the ground terminal of the device. For low-value sense resistors, the  $I \cdot R$  drops in the printed wiring board can be significant and should be taken into account. The use of sockets should be avoided as their contact resistance can cause variations in the effective value of  $R_s$ .

Generally, larger values of  $R_s$  reduce the aforementioned effects but can result in excessive heating and power loss in the

sense resistor. The selected value of  $R_s$  should not cause the absolute maximum voltage rating of 1.0V (0.4V for  $V_{CC}=3.3V_{operation}$ ), for the SENSE terminal, to be exceeded. The current-sensing comparator functions down to ground allowing the device to be used in microstepping, sinusoidal, and other varying current-profile applications.

**(B) Thermal Considerations.**

For reliable operation it is recommended that the maximum junction temperature be kept below 110°C to 125°C. The junction temperature can be measured best by attaching a thermocouple to the power tab/batwing of the device and measuring the tab temperature,  $T_{TAB}$ . The junction temperature can then be approximated by using the formula:

$$T_J \approx T_{TAB} + (I_{LOAD} \cdot 2 \cdot V_F \cdot R_{\theta JT})$$

where  $V_F$  may be chosen from the electrical specification table for the given level of  $I_{LOAD}$ . The value for  $R_{\theta JT}$  is given in the package thermal resistance table for the appropriate package. The power dissipation of the batwing packages can be improved by 20% to 30% by adding a section of printed circuit board copper (typically 6 to 18 square centimeters) connected to the batwing terminals of the device.

The thermal performance in applications that run at high load currents and/or high duty cycles can be improved by adding external diodes in parallel with the internal diodes. In internal PWM slow-decay applications, only the two ground clamp diodes need be added. For internal fast-decay PWM, or external PHASE or ENABLE input PWM applications, all four external diodes should be added for maximum junction temperature reduction.

**(C) PCB Layout.**

The load supply terminal,  $V_{BB}$  should be decoupled with an electrolytic capacitor ( $>47\mu F$  is recommended) placed as close to the device as is physically practical. To minimize the effect of system ground I·R drops on the logic and reference input signals, the system ground should have a low-resistance return to the motor supply voltage.

See also “Current Sensing” and “Thermal Considerations” above.

**(D) Fixed Off-Time Selection.**

With increasing values of  $t_{OFF}$ , switching losses will decrease, low-level load-current regulation will improve, EMI will be reduced, the PWM frequency will decrease, and ripple current will increase. The value of  $t_{OFF}$  can be chosen for optimization of these parameters. For applications where audible noise is a concern, typical values of  $t_{OFF}$  are chosen to be in the range of 15 ms to 35 ms.

**(E) Stepper Motor Applications.**

The MODE terminal can be used to optimize the performance of the device in microstepping/sinusoidal stepper-motor drive applications. When the load current is increasing, slow decay mode is used to limit the switching losses in the device and iron losses in the motor. This also improves the maximum rate at which the load current can increase (as compared to fast decay) due to the slow rate of decay during  $t_{OFF}$ .

When the load current is decreasing, fast-decay mode is used to regulate the load current to the desired level. This prevents tailing of the current profile caused by the back-EMF voltage of the stepper motor.

**Fig. 4 Example of Circuit (including GND) and GND Wiring Pattern**

In stepper-motor applications applying a constant current to the load, slow-decay mode PWM is typically used to limit the switching loss in the device and iron losses in the motor.

#### (F) DC Motor Applications.

In closed-loop systems, the speed of a dc motor can be controlled by PWM of the PHASE or ENABLE inputs, or by varying the reference input voltage (REF). In digital systems (microprocessor controlled), PWM of the PHASE or ENABLE input is used typically thus avoiding the need to generate a variable analog voltage reference. In this case, a dc voltage on the REF input is used typically to limit the maximum load current.

In dc servo applications, which require accurate positioning at low or zero speed, PWM of the PHASE input is selected typically. This simplifies the servo control loop because the transfer function between the duty cycle on the PHASE input and the average voltage applied to the motor is more linear than in the case of ENABLE PWM control (which produces a discontinuous current at low current levels).

With bidirectional dc servo motors, the PHASE terminal can be used for mechanical direction control. Similar to when braking the motor dynamically, abrupt changes in the direction of a rotating motor produces a current generated by the back-EMF. The current generated will depend on the mode of operation. If the internal current control circuitry is not being used, then the maximum load current generated can be approximated by  $I_{LOAD} = (V_{BEMF} + V_{BB}) / R_{LOAD}$  where  $V_{BEMF}$  is proportional to the motor's speed. If the internal slow current-decay control circuitry is used, then the maximum load current generated can be approximated by  $I_{LOAD} = V_{BEMF} / R_{LOAD}$ . For both cases care must be taken to ensure that the maximum ratings of the device are not exceeded. If the internal fast current-decay control circuitry is used, then the load current will regulate to a value given by:

$$I_{LOAD} \approx \frac{V_{REF}}{R_S}$$

**CAUTION:** In fast current-decay mode, when the direction of the motor is changed abruptly, the kinetic energy stored in the motor and load inertia will be converted into current that charges the  $V_{BB}$  supply bulk capacitance (power supply output and decoupling capacitance). Care must be taken to ensure that the capacitance is sufficient to absorb the energy without exceeding the voltage rating of any devices connected to the motor supply.

## Application Notes

### ■Outline

Designed for bidirectional pulse-width modulated current control of inductive loads, the A3952S- is capable of continuous output currents to  $\pm 2A$  and operating voltages to 50V. Internal fixed off-time PWM current-control circuitry can be used to regulate the maximum load current to a desired value. The peak load current limit is set by the user's selection of an input reference voltage and external sensing resistor. The fixed OFF-time pulse duration is set by a user-selected external RC timing network. Internal circuit protection includes thermal shutdown with hysteresis, transient suppression diodes, and crossover-current protection. Special power-up sequencing is not required.

With the ENABLE input held low, the PHASE input controls load current polarity by selecting the appropriate source and sink driver pair. The MODE input determines whether the PWM current-control circuitry operates in a slow current-decay mode (only the selected sink driver switching) or in a fast current-decay mode (selected source and sink switching). A user-selectable blanking window prevents false triggering of the PWM current control circuitry. With the ENABLE input held high, all output drivers are disabled. A sleep mode is provided to reduce power consumption when inactive.

When a logic low is applied to the BRAKE input, the braking function is enabled. This overrides ENABLE and PHASE to turn OFF both source drivers and turn ON both sink drivers. The brake function can be safely used to dynamically brake brush dc motors.

### ■FUNCTIONAL DESCRIPTION

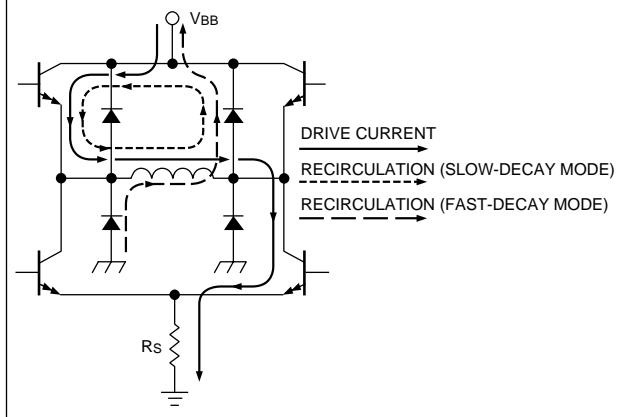

#### (A) INTERNAL PWM CURRENT CONTROL DURING FORWARD AND REVERSE OPERATION

The A3952S- contains a fixed OFF-time pulse-width modulated (PWM) current-control circuit that can be used to limit the load current to a desired value. The value of the current limiting ( $I_{TRIP}$ ) is set by the selection of an external current sensing resistor ( $R_S$ ) and reference input voltage ( $V_{REF}$ ). The internal circuitry compares the voltage across the external sense resistor to one tenth the voltage on the REF input terminal, resulting in a function approximated by

$$I_{TRIP} \approx \frac{V_{REF}}{10 \cdot R_S}$$

In forward or reverse mode the current-control circuitry limits the load current. When the load current reaches  $I_{TRIP}$ , the comparator resets a latch to turn OFF the selected sink driver (in the slow-decay mode) or selected sink and source driver pair (in the fast-decay mode). In slow-decay mode, the selected sink driver is disabled; the load inductance causes the current to recirculate through the source driver and flyback diode (see figure 1). In fast-decay mode, the selected sink and source driver pair are disabled; the load inductance causes the current to flow from ground to the load supply via the ground clamp and flyback diodes.

Fig. 1 Load-Current Paths

The user selects an external resistor ( $R_T$ ) and capacitor ( $C_T$ ) to determine the time period ( $t_{off}=R_T \cdot C_T$ ) during which the drivers remain disabled (see "RC Fixed OFF Time" below). At the end of the  $R_T \cdot C_T$  interval, the drivers are re-enabled allowing the load current to increase again. The PWM cycle repeats, maintaining the load current at the desired value (see figure 2).

Fig. 2 Fast and Slow Current-Decay Waveforms

#### (B) INTERNAL PWM CURRENT CONTROL DURING BRAKE MODE OPERATION

The brake circuit turns OFF both source drivers and turns ON both sink drivers. For dc motor applications, this has the effect of shorting the motor's back-EMF voltage, resulting in current flow that brakes the motor dynamically. However, if the back-EMF voltage is large, and there is no PWM current limiting, then the load current can increase to a value that approaches a locked rotor condition. To limit the current, when the  $I_{TRIP}$  level is reached, the PWM circuit disables the conducting sink driver. The energy stored in the motor's inductance is then discharged into the load supply causing the motor current to decay.

As in the case of forward/reverse operation, the drivers are re-enabled after a time given by  $t_{off}=R_T \cdot C_T$  (see "RC Fixed OFF Time" below). Depending on the back-EMF voltage (proportional to the motor's decreasing speed), the load current again may increase to  $I_{TRIP}$ . If so, the PWM cycle will repeat, limiting the load current to the desired value.

##### (1) Brake Operation-MODE Input High

During braking, when the MODE input is high, the current limit can be approximated by

$$I_{TRIP} \approx \frac{V_{REF}}{10 \cdot R_S}$$

**CAUTION:** Because the kinetic energy stored in the motor and load inertia is being converted into current, which charges the  $V_{BB}$  supply bulk capacitance (power supply output and decoupling capacitance), care must be taken to ensure the capacitance is sufficient to absorb the energy without exceeding the voltage rating of any devices connected to the motor supply.

### (2) Brake Operation-MODE Input Low

During braking, with the MODE input low, the peak current limit defaults internally to a value approximated by

$$I_{TRIP} \approx \frac{1.5V}{R_S}$$

In this mode, the value of  $R_S$  determines the  $I_{TRIP}$  value independent of  $V_{REF}$ . This is useful in applications with differing run and brake currents and no practical method of varying  $V_{REF}$ .

Choosing a small value for  $R_S$  essentially disables the current limiting during braking. Therefore, care should be taken to ensure that the motor's current does not exceed the absolute maximum ratings of the device. The braking current can be measured by using an oscilloscope with a current probe connected to one of the motor's leads.

### (C) RC Fixed OFF Time

The internal PWM current control circuitry uses a one shot to control the time the driver (s) remain (s) OFF. The one shot time,  $t_{off}$  (fixed OFF time), is determined by the selection of an external resistor ( $R_T$ ) and capacitor ( $C_T$ ) connected in parallel from the RC terminal to ground. The fixed OFF time, over a range of values of  $C_T=820pF$  to  $1500pF$  and  $R_T=12k\Omega$  to  $100k\Omega$ , is approximated by

$$t_{OFF} \approx R_T \cdot C_T$$

When the PWM latch is reset by the current comparator, the voltage on the RC terminal will begin to decay from approximately 3 volts. When the voltage on the RC terminal reaches approximately 1.1 volt, the PWM latch is set, thereby re-enabling the driver (s).

### (D) RC Blanking

In addition to determining the fixed OFF-time of the PWM control circuit, the  $C_T$  component sets the comparator blanking time. This function blanks the output of the comparator when the outputs are switched by the internal current control circuitry (or by the PHASE, BRAKE, or ENABLE inputs). The comparator output is blanked to prevent false over-current detections due to reverse recovery currents of the clamp diodes, and/or switching transients related to distributed capacitance in the load.

During internal PWM operation, at the end of the  $t_{off}$  time, the comparator's output is blanked and  $C_T$  begins to be charged from approximately 1.1V by an internal current source of ap-

proximately 1mA. The comparator output remains blanked until the voltage on  $C_T$  reaches approximately 3.0 volts.

Similarly, when a transition of the PHASE input occurs,  $C_T$  is discharged to near ground during the crossover delay time (the crossover delay time is present to prevent simultaneous conduction of the source and sink drivers). After the crossover delay,  $C_T$  is charged by an internal current source of approximately 1mA. The comparator output remains blanked until the voltage on  $C_T$  reaches approximately 3.0 volts.

Similarly, when the device is disabled via the ENABLE input,  $C_T$  is discharged to near ground. When the device is re-enabled,  $C_T$  is charged by the internal current source. The comparator output remains blanked until the voltage on  $C_T$  reaches approximately 3.0V.

For applications that use the internal fast-decay mode PWM operation, the minimum recommended value is  $C_T=1200pF \pm 5\%$ . For all other applications, the minimum recommended value is  $C_T=820pF \pm 5\%$ . These values ensure that the blanking time is sufficient to avoid false trips of the comparator under normal operating conditions. For optimal regulation of the load current, the above values for  $C_T$  are recommended and the value of  $R_T$  can be sized to determine  $t_{off}$ . For more information regarding load current regulation, see below.

### (E) LOAD CURRENT REGULATION WITH THE INTERNAL PWM CURRENT-CONTROL CIRCUITRY

When the device is operating in slow-decay mode, there is a limit to the lowest level that the PWM current-control circuitry can regulate load current. The limitation is the minimum duty cycle, which is a function of the user-selected value of  $t_{off}$  and the maximum value of the minimum ON-time pulse,  $t_{on(min)}$ , that occurs each time the PWM latch is reset. If the motor is not rotating, as in the case of a stepper motor in hold/detent mode, or a brush dc motor when stalled or at startup, the worst-case value of current regulation can be approximated by

$$I_{(AV)} \equiv \frac{[(V_{BB}-V_{SAT(source + sink)}) \cdot t_{on(min) max}] - [1.05 \cdot (V_{SAT(sink)} + V_D) \cdot t_{off}]}{1.05 \cdot (t_{on(min) max} + t_{off}) \cdot R_{LOAD}}$$

where  $t_{off}=R_T \cdot C_T$ ,  $R_{LOAD}$  is the series resistance of the load,  $V_{BB}$  is the load/motor supply voltage, and  $t_{on(min) max}$  is specified in the electrical characteristics table. When the motor is rotating, the back EMF generated will influence the above relationship. For brush dc motor applications, the current regulation is improved. For stepper motor applications when the motor is rotating, the effect is more complex. A discussion of this subject is included in the section on stepper motors under "Applications".

The following procedure can be used to evaluate the worst-case slow-decay internal PWM load current regulation in the system: Set  $V_{REF}$  to 0 volts. With the load connected and the PWM current control operating in slow-decay mode, use an oscilloscope to measure the time the output is low (sink ON) for the output that is chopping. This is the typical minimum ON time ( $t_{on(min) typ}$ ) for the

device.  $C_T$  then should be increased until the measured value of  $t_{on(min)}$  is equal to  $t_{on(min)max}=3.0\mu s$  as specified in the electrical characteristics table. When the new value of  $C_T$  has been set, the value of  $R_T$  should be decreased so the value for  $t_{off}=R_T \cdot C_T$  (with the artificially increased value of  $C_T$ ) is equal to 105% of the nominal design value. The worst-case load current regulation then can be measured in the system under operating conditions.

In applications utilizing both fast-and slow-decay internal PWM modes, the performance of the slow-decay current regulation should be evaluated per the above procedure and a  $t_{on(min)max}$  of  $3.8\mu s$ . This corresponds to a  $C_T$  value of 1200pF, which is required to ensure sufficient blanking during fast-decay internal PWM.

#### (F) LOAD CURRENT REGULATION WITH EXTERNAL PWM OF THE PHASE AND ENABLE INPUTS

The PHASE and ENABLE inputs can be pulse-width modulated to regulate load current. Typical propagation delays from the PHASE and ENABLE inputs to transitions of the power outputs are specified in the electrical characteristics table. If the internal PWM current control is used, then the comparator blanking function is active during phase and enable transitions. This eliminates false tripping of the over-current comparator caused by switching transients (see “RC Blanking” above).

##### (1) ENABLE Pulse-Width Modulation

With the MODE input low, toggling the ENABLE input turns ON and OFF the selected source and sink drivers. The corresponding pair of flyback and ground clamp diodes conduct after the drivers are disabled, resulting in fast current decay. When the device is enabled, the internal current control circuitry will be active and can be used to limit the load current in a slow-decay mode.

For applications that PWM the ENABLE input, and desire that the internal current limiting circuit function in the fast-decay mode, the ENABLE input signal should be inverted and connected to the MODE input. This prevents the device from being switched into sleep mode when the ENABLE input is low.

##### (2) PHASE Pulse-Width Modulation

Toggling the PHASE terminal determines/controls which sink/source pair is enabled, producing a load current that varies with the duty cycle and remains continuous at all times. This can have added benefits in bidirectional brush dc servo motor applications as the transfer function between the duty cycle on the phase input and the average voltage applied to the motor is more linear than in the case of ENABLE PWM control (which produces a discontinuous current at low current levels). See also, “DC Motor Applications” below.

##### (3) SYNCHRONOUS FIXED-FREQUENCY PWM

The internal PWM current-control circuitry of multiple A3952S-devices can be synchronized by using the simple circuit shown in figure 3. A555IC can be used to generate the reset pulse/

blanking signal ( $t_1$ ) and the period of the PWM cycle ( $t_2$ ). The value of  $t_1$  should be a minimum of  $1.5\mu s$  in slow-decay mode and  $2\mu s$  in fast-decay mode. When used in this configuration, the  $R_T$  and  $C_T$  components should be omitted. The PHASE and ENABLE inputs should not be PWMed with this circuit configuration due to the absence of a blanking function synchronous with their transitions.

**Fig. 3 Synchronous Fixed-Frequency Control Circuit**

#### (G) MISCELLANEOUS INFORMATION

A logic high applied to both the ENABLE and MODE terminals puts the device into a sleep mode to minimize current consumption when not in use.

An internally generated dead time prevents crossover currents that can occur when switching phase or braking.

Thermal protection circuitry turns OFF all drivers should the junction temperature reach  $165^\circ C$  (typical). This is intended only to protect the device from failures due to excessive junction temperatures and should not imply that output short circuits are permitted. The hysteresis of the thermal shutdown circuit is approximately  $15^\circ C$ .

If the internal current-control circuitry is not used; the  $V_{REF}$  terminal should be connected to  $V_{CC}$ , the SENSE terminal should be connected to ground, and the RC terminal should be left floating (no connection).

An internal under-voltage lockout circuit prevents simultaneous conduction of the outputs when the device is powered up or powered down.

## ■ APPLICATION NOTES

### (A) Current Sensing

The actual peak load current ( $I_{OUTP}$ ) will be greater than the calculated value of  $I_{TRIP}$  due to delays in the turn OFF of the drivers. The amount of overshoot can be approximated as

$$I_{OUTP} \approx \frac{(V_{BB} - [(I_{TRIP} \cdot R_{LOAD}) + V_{BEMF}]) \cdot t_{pd(pwm)}}{L_{LOAD}}$$

where  $V_{BB}$  is the load/motor supply voltage,  $V_{BEMF}$  is the back-EMF voltage of the load,  $R_{LOAD}$  and  $L_{LOAD}$  are the resistance and inductance of the load respectively, and  $t_{pd(pwm)}$  is the propagation delay as specified in the electrical characteristics table.

The reference terminal has an equivalent input resistance of  $50k\Omega \pm 30\%$ . This should be taken into account when determining the impedance of the external circuit that sets the reference voltage value.

To minimize current-sensing inaccuracies caused by ground trace IR drops, the current-sensing resistor should have a separate return to the ground terminal of the device. For low-value sense resistors, the IR drops in the PCB can be significant and should be taken into account. The use of sockets should be avoided as their contact resistance can cause variations in the effective value of  $R_s$ .

Larger values of  $R_s$  reduce the aforementioned effects but can result in excessive heating and power loss in the sense resistor. The selected value of  $R_s$  must not cause the SENSE terminal absolute maximum voltage rating to be exceeded. The recommended value of  $R_s$  is in the range of

$$R_s \approx \frac{(0.375 \text{ to } 1.125)}{I_{TRIP}}$$

The current-sensing comparator functions down to ground allowing the device to be used in microstepping, sinusoidal, and other varying current profile applications.

### (B) Thermal Considerations

For reliable operation, it is recommended that the maximum junction temperature be kept as low as possible, typically  $90^\circ\text{C}$  to  $125^\circ\text{C}$ . The junction temperature can be measured by attaching a thermocouple to the power tab/batwing of the device and measuring the tab temperature,  $T_T$ . The junction temperature can then be approximated by using the formula

$$T_J \approx T_T + (2V_F I_{OUT} R_{\theta JT})$$

where  $V_F$  is the clamp diode forward voltage and can be determined from the electrical specification table for the given level of  $I_{OUT}$ . The value for  $R_{\theta JT}$  is given in the package thermal resistance table for the appropriate package.

The power dissipation of the batwing packages can be improved by 20 to 30% by adding a section of printed circuit board copper (typically 6 to 18 square centimeters) connected to the batwing terminals of the device.

The thermal performance in applications with high load currents and/or high duty cycles can be improved by adding external diodes in parallel with the internal diodes. In internal PWM slow-decay applications, only the tow top-side (flyback) diodes need be added. For internal fast-decay PWM, or external PHASE or ENABLE input PWM applications, all four external diodes should be added for maximum junction temperature reduction.

### (C) PCB Layout

The load supply terminal,  $V_{BB}$ , should be decoupled ( $>47\mu\text{F}$  electrolytic and  $0.1\mu\text{F}$  ceramic capacitors are recommended) as close to the device as is physically practical. To minimize the effect of system ground I·R drops on the logic and reference input signals, the system ground should have a low-resistance return to the load supply voltage.

See also "Current Sensing" and "Thermal Considerations" above.

### (D) Fixed Off-Time Selection

With increasing values of  $t_{off}$ , switching losses decrease, low-level load-current regulation improves, EMI is reduced, the PWM frequency will decrease, and ripple current will increase. The value of  $t_{off}$  can be chosen for optimization of these parameters. For applications where audible noise is a concern, typical values of  $t_{off}$  are chosen to be in the range of 15 to  $35\mu\text{s}$ .

### (E) Stepper Motor Applications

The MODE terminal can be used to optimize the performance of the device in microstepping/sinusoidal stepper motor drive applications. When the average load current is increasing, slow-decay mode is used to limit the switching losses in the device and iron losses in the motor.

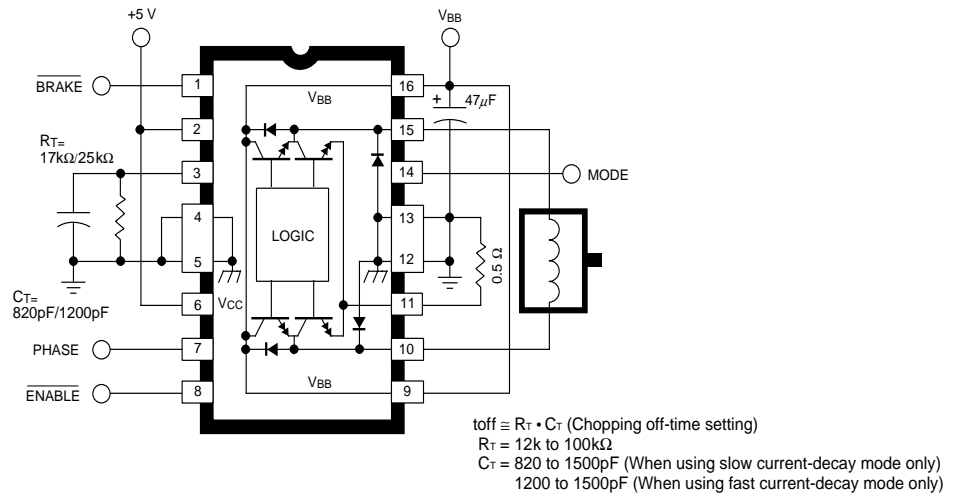

This also improves the maximum rate at which the load current can increase (as compared to fast decay) due to the slow rate of decay during  $t_{off}$ . When the average load current is decreasing, fast-decay mode is used to regulate the load current to the desired level. This prevents tailing of the current profile caused by the back-EMF voltage of the stepper motor.

In stepper motor applications applying a constant current to the load, slow-decay mode PWM is used typically to limit the switching losses in the device and iron losses in the motor.

Fig. 5 Example of DC motor drive

# 2-Phase Stepper Motor Bipolar Driver ICs

Allegro MicroSystems product

## Features

- Fixed off-time PWM current control
- Internal 1/3 and 2/3 reference divider
- 1-phase/2-phase/W1-2 phase excitation mode with digital input
- Microstepping with reference input
- Low saturation voltage (Sink transistor)
- Internal thermal shutdown circuitry
- Internal crossover-current protection circuitry
- Internal UVLO protection
- Internal transient-suppression diodes
- Low thermal resistance package

## Absolute Maximum Ratings

Parameter	Symbol	Conditions	Ratings		Units
			UDN2916B	UDN2916LB	
Motor supply voltage	$V_{BB}$		45		V
Output current (peak)	$I_{O(peak)}$	$tw \leq 20 \mu s$	$\pm 1.0$		A
Output current (continuous)	$I_O$		$\pm 0.75$		A
Logic supply voltage	$V_{CC}$		7.0		V
Logic input voltage range	$V_{IN}$		-0.3 to +7.0		V
Output emitter voltage	$V_E$		1.5		V
Package power dissipation	$P_D$ (Note1)		3.12	2.27	W
Operating temperature	$T_a$		-20 to +85		$^{\circ}C$
Junction temperature	$T_j$ (Note2)		+150		$^{\circ}C$
Storage temperature	$T_{stg}$		-55 to +150		$^{\circ}C$

● Output current rating may be limited by duty cycle, ambient temperature, and heat sinking. Under any set of conditions, do not exceed the specified current rating or a junction temperature of 150°C.

Note 1: When ambient temperature is 25°C or over, derate using -25mW/°C (UDN2916B) or -18.2mW/°C (UDN2916LB).

Note 2: Fault conditions where junction temperature ( $T_j$ ) exceeds 150°C will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

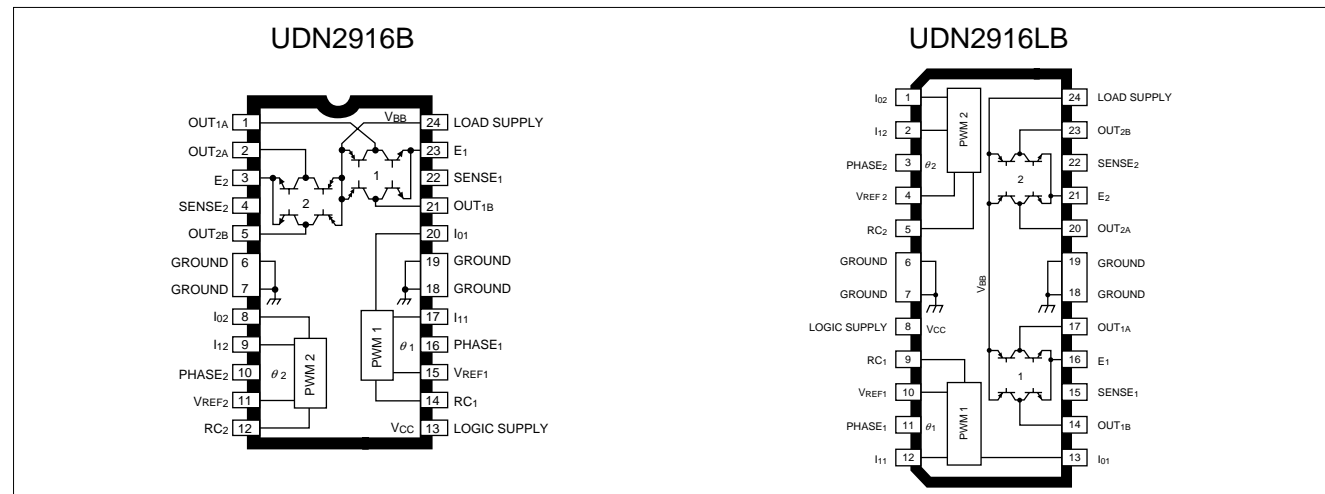

## Electrical Characteristics

(Unless specified otherwise,  $T_a=25^{\circ}C$ ,  $V_{BB}=45V$ ,  $V_{CC}=4.75V$  to  $5.25V$ ,  $V_{REF}=5.0V$ )

## Application Notes

### ●PWM CURRENT CONTROL

The UDN2916B/LB dual bridges are designed to drive both windings of a bipolar stepper motor. Output current is sensed and controlled independently in each bridge by an external sense resistor ( $R_s$ ), internal comparator, and monostable multivibrator.

When the bridge is turned ON, current increases in the motor winding and it is sensed by the external sense resistor until the sense voltage ( $V_{SENSE}$ ) reaches the level set at the comparator's input:

$$I_{TRIP} = V_{REF} / 10R_S$$

The comparator then triggers the monostable which turns OFF the source driver of the bridge. The actual load current peak will be slightly higher than the trip point (especially for low-inductance loads) because of the internal logic and switching delays. This delay ( $t_d$ ) is typically  $2\mu s$ . After turn-off, the motor current decays, circulating through the ground-clamp diode and sink transistor. The source driver's OFF time (and therefore the magnitude of the current decrease) is determined by the monostable's external RC timing components, where  $t_{off} = R_T C_T$  within the range of  $20k\Omega$  to  $100k\Omega$  and  $100pF$  to  $1000 pF$ .

When the source driver is re-enabled, the winding current (the sense voltage) is again allowed to rise to the comparator's threshold. This cycle repeats itself, maintaining the average motor winding current at the desired level.

Loads with high distributed capacitances may result in high turn-ON current peaks. This peak (appearing across  $R_s$ ) will attempt to trip the comparator, resulting in erroneous current control or high-frequency oscillations. An external  $R_c C_c$  time delay should be used to further delay the action of the comparator. Depending on load type, many applications will not require these external components (SENSE connected to E.)

### ●LOGIC CONTROL OF OUTPUT CURRENT

Two logic level inputs ( $I_0$  and  $I_1$ ) allow digital selection of the motor winding current at 100%, 67%, 33%, or 0% of the maximum level per the table. The 0% output current condition turns OFF all drivers in the bridge and can be used as an OUTPUT ENABLE function.

These logic level inputs greatly enhance the implementation of  $\mu P$ -controlled drive formats.

During half-step operations, the  $I_0$  and  $I_1$  allow the  $\mu P$  to control the motor at a constant torque between all positions in an eight-step sequence. This is accomplished by digitally selecting 100% drive current when only one phase is ON and 67% drive current when two phases are ON. Logic highs on both  $I_0$  and  $I_1$  turn OFF all drivers to allow rapid current decay when switching phases. This helps to ensure proper motor operation at high step rates.

The logic control inputs can also be used to select a reduced current level (and reduced power dissipation) for 'hold' conditions and/or increased current (and available torque) for start-up conditions.

### ●SWITCHING THE EXCITATION CURRENT DIRECTION

The PHASE input to each bridge determines the direction motor winding current flows. An internally generated deadtime (approximately  $2\mu s$ ) prevents crossover currents that can occur when switching the PHASE input.

**●REDUCTION AND DISPERSION OF POWER LOSS**

The thermal performance can be improved by adding four external Schottky barrier diodes (AK03 or other) between each output terminal and ground. In most applications, the chopping ON time is shorter than the chopping OFF time (small ON duty). Therefore, a great part of the power loss of the driver IC is attributable to the motor regenerative current during the chopping OFF period. The regenerative current from the motor flows through the current sensing resistor and ground clamp diode and returns to the motor. The voltage drop across this path causes the power loss. On this path, the forward voltage  $V_F$  of ground clamp diode shows the greatest drop. This means that adding Schottky barrier diodes will improve the thermal performance if their  $V_F$  characteristic is smaller than that of the internal ground clamp diode.

The external diodes also disperse the loss (a source of heat) and reduce the package power dissipation  $P_D$  of the driver IC. Consequently, a greater output current can be obtained.

**●CONTROL SEQUENCE OF 1-2 OR W1-2 PHASE EXCITATION**

To reduce vibration when the stepper motor is rotating, the UDN2916B/LB can provide 1-2 or W1-2 phase excitation for the control sequence without varying the  $V_{REF}$  terminal voltage. The step angle is

1/2 step : 1-2 excitation

About 1/4 step : W1-2 excitation

The control sequence is as shown below. (This sequence uses threshold signal terminals  $I_0$  and  $I_1$  for PWM current control.)

**Control sequence (1-2/W1-2 phase)**

(TABLE 1= ENABLE2= 0)

Sequence No.	Phase A				Phase B				1-2 phase excitation	W1-2 phase excitation
	PH1	I11	I01	Current ratio	PH2	I12	I02	Current ratio		
0	0	0	0	1	X	1	1	0	*	*
1	0	0	0	1	0	1	0	1/3		*
2	0	0	1	2/3	0	0	1	2/3	*	*
3	0	1	0	1/3	0	0	0	1		*

11	1	1	0	1/3	1	0	0	1		*
12	X	1	1	0	1	0	0	1	*	*
13	0	1	0	1/3	1	0	0	1		*
14	0	0	1	2/3	1	0	1	2/3	*	*
15	0	0	0	0	1	1	0	1/3		*

Note: When the sequence no. is 0, 4, 8, or 12, power-down can be set as follows  
 I11=1, I01=0: Sequence No. 0 or 8  
 I12=1, I02=0: Sequence No. 4 or 12  
 If power-down is necessary for a sequence other than 0, 4, 8, or 12, lower the  $V_{REF}$  terminal voltage. However, do not set the voltage lower than the lower limit of the setting range.

### ●MICROSTEPPING (1/8 STEP) CONTROL SEQUENCE

Varying the  $V_{REF}$  terminal voltage in steps provides 1/8

microstepping and reduces motor vibration greatly. The microstepping control sequence is as follows:

#### Control sequence (microstepping)

Sequence No.	Phase A					Phase B				
	PH1	$V_{REF1}$ (V)	$I_{11}$	$I_{01}$	Current ratio (%)	PH2	$V_{REF2}$ (V)	$I_{12}$	$I_{02}$	Current ratio (%)
0	0	7.5	0	0	100	X	1.5	1	1	0
1	0	7.4	0	0	98	0	1.5	0	0	20
2	0	6.9	0	0	92	0	2.9	0	0	38
3	0	6.2	0	0	83	0	4.2	0	0	56
4	0	5.3	0	0	71	0	5.3	0	0	71
5	0	4.2	0	0	56	0	6.2	0	0	83
6	0	2.9	0	0	38	0	6.9	0	0	92
7	0	1.5	0	0	20	0	7.4	0	0	98
8	X	1.5	1	1	0	0	7.5	0	0	100
9	1	1.5	0	0	20	0	7.4	0	0	98
10	1	2.9	0	0	38	0	6.9	0	0	92
11	1	4.2	0	0	56	0	6.2	0	0	83
12	1	5.3	0	0	71	0	5.3	0	0	71
13	1	6.2	0	0	83	0	4.2	0	0	56
14	1	6.9	0	0	92	0	2.9	0	0	38
15	1	7.4	0	0	98	0	1.5	0	0	20
16	1	7.5	0	0	100	X	1.5	1	1	0
17	1	7.4	0	0	98	1	1.5	0	0	20
18	1	6.9	0	0	92	1	2.9	0	0	38
19	1	6.2	0	0	83	1	4.2	0	0	56
20	1	5.3	0	0	71	1	5.3	0	0	71
21	1	4.2	0	0	56	1	6.2	0	0	83
22	1	2.9	0	0	38	1	6.9	0	0	92
23	1	1.5	0	0	20	1	7.4	0	0	98
24	X	1.5	1	1	0	1	7.5	0	0	100
25	0	1.5	0	0	20	1	7.4	0	0	98
26	0	2.9	0	0	38	1	6.9	0	0	92
27	0	4.2	0	0	56	1	6.2	0	0	83
28	0	5.3	0	0	71	1	5.3	0	0	71
29	0	6.2	0	0	83	1	4.2	0	0	56
30	0	6.9	0	0	92	1	2.9	0	0	38
31	0	7.4	0	0	98	1	1.5	0	0	20

Note: The  $V_{REF}$  terminal voltage cannot be set to 0 V. To make the output current ratio 0%, set  $I_{0X}=I_{1X}=1$ .

When the sequence is 0, 8, 16, or 24, power-down can be set as follows:

$I_{11}=1, I_{01}=0$ : Sequence No. 0 or 16

$I_{12}=1, I_{02}=0$ : Sequence No. 8 or 24

#### ● $V_{REF}$ terminal

$V_{REF}$  is the reference voltage input terminal for PWM constant current control. To realize stable ensure a stable signal, make sure noise is not applied to the terminal.

#### ● $V_{BB}$ terminal

To prevent voltage spikes on the load power supply terminal ( $V_{BB}$ ), connect a large capacitor ( $\geq 22\mu\text{F}$ ) between the  $V_{BB}$  terminal and ground as close to the device as possible. Make sure the load supply voltage does not exceed 45 V.

#### ●Thermal protection

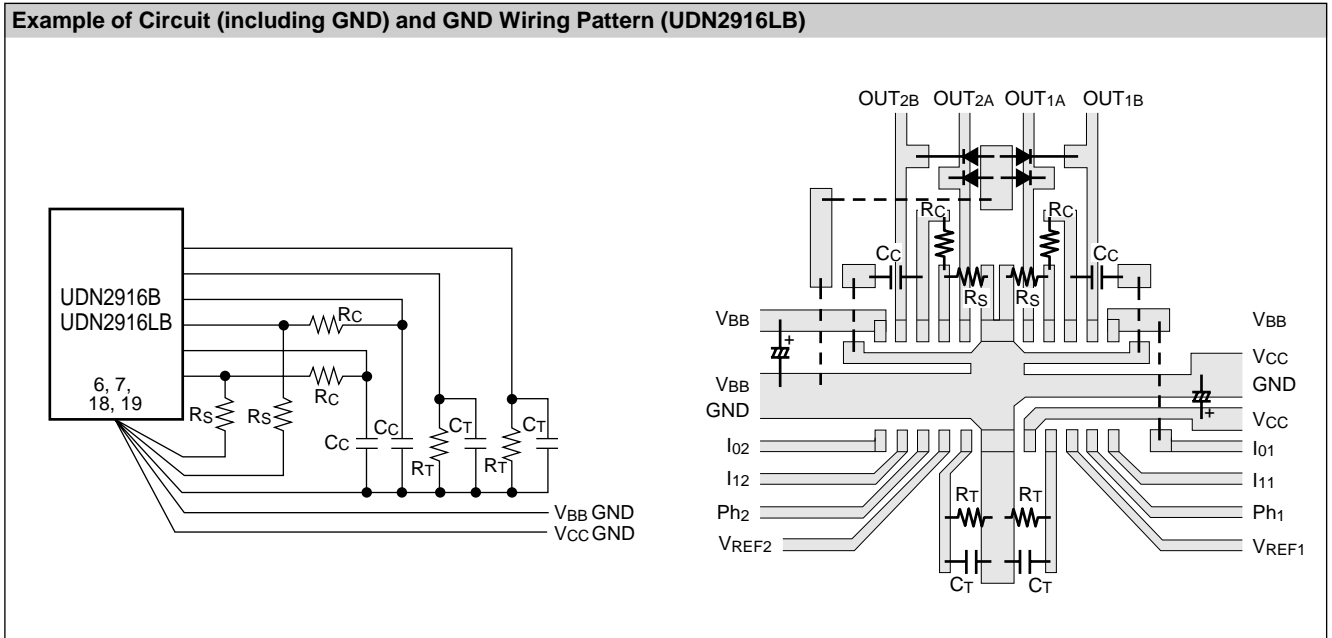

Thermal protection circuitry turns OFF all drivers when the junction temperature reaches  $+170^\circ\text{C}$ . It is only intended to protect the device from failures due to excessive junction temperature and should not imply that output short circuits are permitted. The output drivers are re-enabled when the junction temperature cools to  $+145^\circ\text{C}$ .

● **Around the ground**

Since the UDN2916B/LB is a chopping type power driver IC, take great care around the ground when mounting. Separate

the power system and the small signal (analog) system. Provide a single-point connection to the GND terminal or a solid pattern of low enough impedance.

**Example of Circuit (including GND) and GND Wiring Pattern (UDN2916LB)**

# 2-Phase Stepper Motor Bipolar Driver IC

Allegro MicroSystems product

## Features

- Fixed off-time PWM current control
- Internal 1/3 and 2/3 reference divider
- 1-phase/2-phase/W1-2 phase excitation mode with digital input
- Microstepping with reference input
- Low saturation voltage (Sink transistor)
- Internal thermal shutdown circuitry
- Internal crossover-current protection circuitry
- Internal UVLO protection
- Internal transient-suppression diodes
- Low thermal resistance 44-pin PLCC

## Absolute Maximum Ratings

Parameter	Symbol	Conditions	Ratings	Units
Motor supply voltage	V <sub>BB</sub>		45	V
Output current (peak)	I <sub>O (peak)</sub>	tw≤20μs	±1.75	A
Output current (continuous)	I <sub>O</sub>		±1.5	A
Logic supply voltage	V <sub>CC</sub>		7.0	V
Logic input voltage range	V <sub>IN</sub>		-0.3 to +7.0	V
Output emitter voltage	V <sub>E</sub>		1.0	V
Package power dissipation	P <sub>D</sub> (Note1)		4.16	W
Operating temperature	T <sub>a</sub>		-20 to +85	°C
Junction temperature	T <sub>J</sub> (Note2)		+150	°C
Storage temperature	T <sub>stg</sub>		-55 to +150	°C

● Output current rating may be limited by duty cycle, ambient temperature, and heat sinking. Under any set of conditions, do not exceed the specified current rating or a junction temperature of 150°C.

Note 1: When ambient temperature is 25°C or over, derate using -33.3mW/°C.

Note 2: Fault conditions where junction temperature (T<sub>J</sub>) exceeds 150°C will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

## Electrical Characteristics

(Unless specified otherwise, T<sub>a</sub>=25°C, V<sub>BB</sub>=45V, V<sub>CC</sub>=5.0V, V<sub>REF</sub>=5.0V)

## Application Notes

### ●REDUCTION AND DISPERSION OF POWER LOSS

The thermal performance can be improved by adding four external Schottky barrier diodes (EK13 or other) between each output terminal and ground. In most applications, the chopping ON time is shorter than the chopping OFF time (small ON duty). Therefore, a great part of the power loss of the driver IC is attributable to the motor regenerative current during the chopping OFF period. The regenerative current from the motor flows through the current sensing resistor and ground clamp diode and returns to the motor. The voltage drop across this path causes the power loss. On this path, the forward voltage  $V_F$  of ground clamp diode shows the greatest drop. This means that adding Schottky barrier diodes will improve the thermal performance if their  $V_F$  characteristic is smaller than that of the internal ground clamp diode.

The external diodes also disperse the loss (a source of heat) and reduce the package power dissipation  $P_D$  of the driver IC. Consequently, a greater output current can be obtained.

### ●CONTROL SEQUENCE OF 1-2 OR W1-2 PHASE EXCITATION

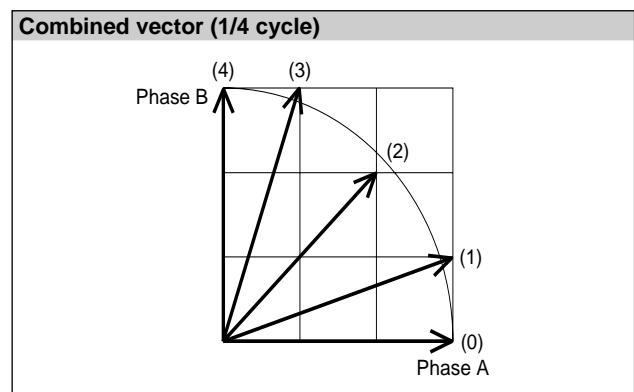

To reduce vibration when the stepper motor is rotating, the UDN2917EB can provide 1-2 or W1-2 phase excitation for the control sequence without varying the  $V_{REF}$  terminal voltage.

The step angle is

1/2 step : 1-2 excitation

About 1/4 step : W1-2 excitation

The control sequence is as shown below. (This sequence uses threshold signal terminals  $I_0$  and  $I_1$  for PWM current control.)

### Control sequence (1-2/W1-2 phase)

(ENABLE 1= ENABLE 2=0)

Sequence No.	Phase A				Phase B				1-2 phase excitation	W1-2 phase excitation
	PH <sub>1</sub>	I <sub>11</sub>	I <sub>01</sub>	Current ratio	PH <sub>2</sub>	I <sub>12</sub>	I <sub>02</sub>	Current ratio		
0	0	0	0	1	X	1	1	0	*	*
1	0	0	0	1	0	1	0	1/3	*	*
2	0	0	1	2/3	0	0	1	2/3	*	*
3	0	1	0	1/3	0	0	0	1	*	*
4	X	1	1	0	0	0	0	1	*	*
5	1	1	0	1/3	0	0	0	1	*	*

7	1	0	0	1	0	1	0	1/3	*	*
8	1	0	0	1	X	1	1	0	*	*
9	1	0	0	1	1	1	0	1/3	*	*
10	1	0	1	2/3	1	0	1	2/3	*	*
11	1	1	0	1/3	1	0	0	1	*	*
12	X	1	1	0	1	0	0	1	*	*
13	0	1	0	1/3	1	0	0	1	*	*
14	0	0	1	2/3	1	0	1	2/3	*	*
15	0	0	0	0	1	1	0	1/3	*	*

Note: When the sequence no. is 0, 4, 8, or 12, power-down can be set as follows

I<sub>11</sub>=1, I<sub>01</sub>=0: Sequence No. 0 or 8

I<sub>12</sub>=1, I<sub>02</sub>=0: Sequence No. 4 or 12

If power-down is necessary for a sequence other than 0, 4, 8, or 12, lower the

$V_{REF}$  terminal voltage. However, do not set the voltage lower than the lower limit of the setting range.

### ●MICROSTEPPING (1/8 STEP) CONTROL SEQUENCE

Varying the  $V_{REF}$  terminal voltage in steps provides 1/8

microstepping and reduces motor vibration greatly. The microstepping control sequence is as follows:

#### Control sequence (microstepping)

( $\overline{ENABLE1} = \overline{ENABLE2} = 0$ )

Sequence No.	Phase A					Phase B				
	PH1	$V_{REF1}$ (V)	$I_{11}$	$I_{01}$	Current ratio (%)	PH2	$V_{REF2}$ (V)	$I_{12}$	$I_{02}$	Current ratio (%)

26	0	2.9	0	0	38	1	6.9	0	0	92
27	0	4.2	0	0	56	1	6.2	0	0	83
28	0	5.3	0	0	71	1	5.3	0	0	71
29	0	6.2	0	0	83	1	4.2	0	0	56
30	0	6.9	0	0	92	1	2.9	0	0	38
31	0	7.4	0	0	98	1	1.5	0	0	20

Note: The  $V_{REF}$  terminal voltage cannot be set to 0 V. To make the output current ratio 0%, set  $I_{0X} = I_{1X} = 1$ .

When the sequence is 0, 8, 16, or 24, power-down can be set as follows:

$I_{11} = 1, I_{01} = 0$ : Sequence No. 0 or 16

$I_{12} = 1, I_{02} = 0$ : Sequence No. 8 or 24

### ● $V_{REF}$ terminal

$V_{REF}$  is the reference voltage input terminal for PWM constant current control. To realize stable ensure a stable signal, make sure noise is not applied to the terminal.

### ● $V_{BB}$ terminal

To prevent voltage spikes on the load power supply terminal ( $V_{BB}$ ), connect a large capacitor ( $\geq 47\mu\text{F}$ ) between the  $V_{BB}$  terminal and ground as close to the device as possible. Make sure the load supply voltage does not exceed 45V.

### ●Thermal protection

Thermal protection circuitry turns OFF all drivers when the junction temperature reaches  $+170^\circ\text{C}$ . It is only intended to protect the device from failures due to excessive junction temperature and should not imply that output short circuits are permitted. The output drivers are re-enabled when the junction temperature cools to  $+145^\circ\text{C}$ .

### ●Around the ground

Since the UDN2917EB is a chopping type power driver IC, take great care around the ground when mounting. Separate the power system and the small signal (analog) system. Provide a single-point connection to the GND terminal or a solid pattern of low enough impedance.

# 2-Phase Stepper Motor Bipolar Driver ICs

Allegro MicroSystems product

## ■ Features

- Maximum output ratings: 50V,  $\pm 1.5$ A
- Internal 3-bit non-linear DAC for 8-division microstepping enables 2W1-2, W1-2, 1-2, 2-phase excitation drive without external sine wave generator
- Internal PWM current control in Mixed Decay mode (can also be used in Fast Decay and Slow Decay mode), which improves motor current response and stability without deterioration of motor iron loss
- External RC filter for sense terminal not required thanks to internal blanking circuitry
- Internal thermal shutdown, crossover-current protection and transient-suppression diodes
- Special power-up and power-down sequencing for motor supply and logic supply not required
- Employs copper batwing lead frame with low thermal resistance

## ■ Absolute Maximum Ratings

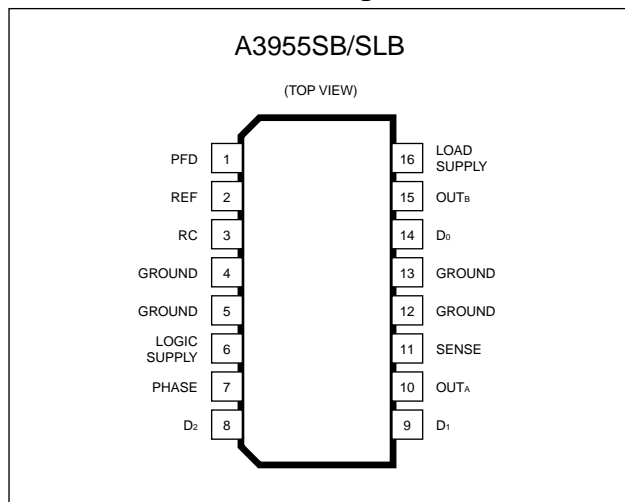

Parameter	Symbol	Ratings		Units
		A3955SB	A3955SLB	
Load supply voltage	$V_{BB}$	50		V
Output current (continuous)	$I_o$	$\pm 1.5$		A
Logic supply voltage	$V_{CC}$	7.0		V
Logic/reference input voltage range	$V_{IN}$	-0.3 to $V_{CC}+0.3$		V
Sense voltage	$V_S$	1.0		V
Package power dissipation	$P_D$ (Note1)	2.90	1.86	W
Operating temperature	$T_a$	-20 to +85		°C
Junction temperature	$T_j$ (Note2)	+150		°C
Storage temperature	$T_{stg}$	-55 to +150		°C

● Output current rating may be limited by duty cycle, ambient temperature, and heat sinking. Under any set of conditions, do not exceed the specified current rating or a junction temperature of 150°C.

Note 1: When ambient temperature is 25°C or over, derate using -23.26mW/°C(SB) or -14.93mW/°C(SLB).

Note 2: Fault conditions where junction temperature ( $T_j$ ) exceeds 150°C will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

■ Current Vector Locus

External Dimensions

(Unit: mm)

# 2-Phase Stepper Motor Bipolar Driver IC

Allegro MicroSystems product

## ■ Features

- Maximum output ratings: 50V,  $\pm 1.5$ A
- Internal 4-bit non-linear DAC for 16-division microstepping enables 4W1-2, 2W1-2, W1-2, 2-phase excitation drive without external sine wave generator
- Internal PWM current control in Mixed Decay mode (can also be used in Fast Decay and Slow Decay mode), which improves motor current response and stability without deterioration of motor iron loss
- External RC filter for sense terminal not required thanks to internal blanking circuitry
- Internal thermal shutdown, crossover-current protection and transient-suppression diodes
- Special power-up and power-down sequencing for motor supply and logic supply not required
- Employs copper batwing lead frame with low thermal resistance

## ■ Absolute Maximum Ratings

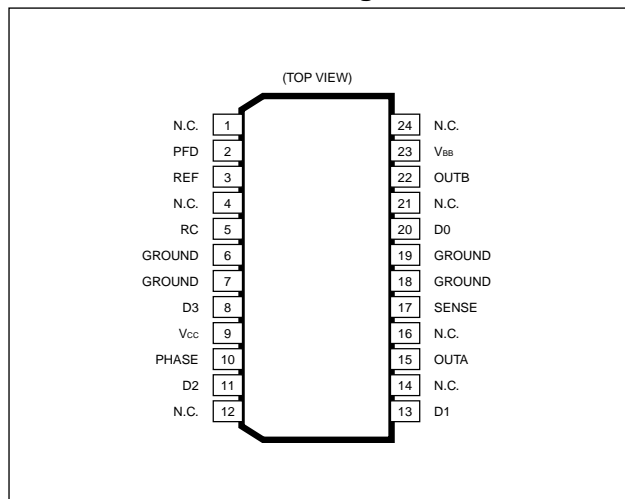

Parameter	Symbol	Ratings	Units
Load supply voltage	$V_{BB}$	50	V
Output current (continuous)	$I_o$	$\pm 1.5$	A
Logic supply voltage	$V_{CC}$	7.0	V
Logic/reference input voltage range	$V_{IN}$	-0.3 to $V_{CC}+0.3$	V
Sense voltage	$V_S$	1.0	V
Package power dissipation	$P_D$ (Note1)	2.23	W
Operating temperature	$T_a$	-20 to +85	$^{\circ}\text{C}$
Junction temperature	$T_j$ (Note2)	+150	$^{\circ}\text{C}$
Storage temperature	$T_{stg}$	-55 to +150	$^{\circ}\text{C}$

● Output current rating may be limited by duty cycle, ambient temperature, and heat sinking. Under any set of conditions, do not exceed the specified current rating or a junction temperature of 150 $^{\circ}\text{C}$ .

Note 1: When ambient temperature is 25 $^{\circ}\text{C}$  or over, derate using -17.86mW/ $^{\circ}\text{C}$ .

Note 2: Fault conditions where junction temperature ( $T_j$ ) exceeds 150 $^{\circ}\text{C}$  will activate the device's thermal shutdown circuitry. These conditions can be tolerated but should be avoided.

Terminal Connection

The package shapes of SI-7600 and SI-7600D are different, however the terminal connection is the same.

External Dimensions (Unless specified otherwise, all values are typical)

(Units: mm)

## Application Notes

### 1. Outline

The SI-7600/SI-7600D is a control IC used with a power MOS FET array to drive a 3-phase stepper motor. Select the output-stage MOS FET according to the rated current of the motor. The full step is 2-phase excitation when this IC is in a star connection but 3-phase excitation when it is in a delta connection.

### 2. Features

- Suitable for both star connection drive and delta connection drive
- Maximum load supply voltage  $V_{BB}=45V$
- Control logic supply voltage  $V_{CC}=3$  to  $5.5V$
- Supports star connection (2/2-3phase excitation) and delta connection (3/2-3phase excitation)
- Step switching timing by clock signal input
- Forward/reverse, hold, and motor-free control
- Step switching at the positive edge or positive/negative edge of the clock signal
- Control current automatic switching function for 2-3phase excitation (effective for star connection)  
(Current control: 86% for 2-phase excitation, 100% for 3-phase excitation)
- Self-excitation constant-current chopping by external C/R
- Slow Decay, Mixed Decay, or Fast Decay selectable
- Two package lineup: SOP (surface mounting) and DIP (lead insertion)  
SOP...SI-7600, DIP...SI-7600D
- Maximum output current depends on the ratings of the MOS FET array used

### 3. Input Logic Truth Table

Input terminal	Low level	High level
CW/CCW	CW	CCW
Full/Half	2-3phase excitation	2-phase excitation
Enable	Disable	Enable
Mode (Note 1)	Always 100%	2-phase excitation: 85% 3-phase excitation: 100%
Edge (Note 2)	Positive	Positive/negative
Reset (Note 3)	Enable	Internal logic reset output disable

Select CW/CCW, Full/Half, or Edge when the clock level is low.

Note 1: The control current is always 85% for the full step (2-phase excitation) when the Mode terminal level is high. The value of 100% control current is calculated at the  $V_{REF}/(5 \times R_S)$  terminal because a 1/5 buffer is built into the reference section.

Note 2: When the Edge terminal level is set high, the internal counter increments both at the rising and falling edges. Therefore, the duty ratio of the input clock should be set at 50%.

Note 3: When the Reset terminal level is set high, the internal

counter is reset. Output remains disabled as long as the Reset terminal level is high.

### 4. Determining the control current

The control current  $I_O$  can be calculated as follows:

When the Mode terminal level is low

$$I_O \cong V_{REF}/(5 \times R_S)$$

When the Mode terminal level is high

$$I_O \cong V_{REF}/(5 \times R_S) \rightarrow \text{3-phase excitation}$$

$$I_O \cong V_{REF}/(5.88 \times R_S) \rightarrow \text{2-phase excitation}$$

The reference voltage can be set within the range of 0.2V to  $V_{CC} - 2V$ . (When the voltage is less than 0.2V, the accuracy of the reference voltage divider ratio deteriorates.)

### 5. About the Current Control System (Setting the Constant Ct/Rt)

The SI-7600 uses a current control system of the self-excitation type with a fixed chopping OFF time.

The chopping OFF time is determined by the constant Ct/Rt.

The constant Ct/Rt is calculated by the formula

$$T_{OFF} \cong 1.1 \times C_T \times R_T \dots \dots (1)$$

The recommended range of constant Ct/Rt is as follows:

Ct: 420 to 1100pF

Rt: 15 to 75k $\Omega$

(Slow Decay or Mixed Decay  $\rightarrow$  560pF/47k $\Omega$ , Fast Decay  $\rightarrow$  470pF/20k $\Omega$ )

Usually, set  $T_{OFF}$  to a value where the chopping frequency becomes about 30 to 40kHz.

The mode can be set to Slow Decay, Fast Decay, or Mixed Decay depending on the PFD terminal input potential.

PFD applied voltage and decay mode

PFD applied voltage	Decay mode
0 to 0.3V	Fast Decay
0.7V to 1.3V	Mixed Decay
1.7V to $V_{CC}$	Slow Decay

In Mixed Decay mode, the Fast/Slow time ratio can be set using the voltage applied to the PFD terminal. The calculated values are summarized below.

In this mode, the point of switching from Fast Decay to Slow Decay is determined by the RC terminal voltage that determines the chopping OFF time and by the PFD input voltage  $V_{PFD}$ .

Formula (1) is used to determine the chopping OFF time.

The Fast Decay time is then determined by the RC discharge time from the RC voltage (about 1.5V) to the PFD input voltage ( $V_{PFD}$ ) when chopping is turned from ON to OFF.

The Fast Decay time is

$$t_{OFF1} \cong -R_T \times C_T \times \ln \left( \frac{V_{PFD}}{1.5} \right) \dots \dots (2)$$

The Slow Decay time ( $t_{OFF2}$ ) is calculated by subtracting the value of (2) from that of (1).

$$t_{OFF2} \cong T_{OFF} - t_{OFF1} \dots \dots (3)$$

## 6. Method of Calculating Power Loss of Output MOS FET

The SI-7600 uses a MOS-FET array for output. The power loss of this MOS FET array can be calculated as summarized below. This is an approximate value that does not reflect parameter variations or other factors during use in the actual application. Therefore, heat from the MOS FET array should actually be measured.

### ● Parameters for calculating power loss

To calculate the power loss of the MOS FET array, the following parameters are needed:

- (1) Control current  $I_o$  (max)
- (2) Excitation method
- (3) Chopping ON-OFF time at current control:  $T_{ON}$ ,  $T_{OFF}$ ,  $t_{OFF}$   
( $T_{ON}$ : ON time,  $T_{OFF}$ : OFF time,  $t_{OFF}$ : Fast Decay time at OFF)

(4) ON resistance of MOS FET:  $R_{DS(ON)}$

(5) Forward voltage of MOS FET body diode:  $V_{SD}$

For (4) and (5), use the maximum values of the MOS FET specifications.

(3) should be confirmed on the actual application.

### ● Power loss of Pch MOS FETs

The power loss of Pch MOS FETs is caused by the ON resistance and by the chopping-OFF regenerative current flowing through the body diodes in Fast Decay mode.

(In Slow Decay mode, the chopping-OFF regenerative current does not flow the body diodes.)

The losses are

ON resistance loss P1:  $P1 = I_M^2 \times R_{DS(ON)}$

Body diode loss P2:  $P2 = I_M \times V_{SD}$

With these parameters, the loss  $P_p$  per MOS FET is calculated depending on the actual excitation method as follows:

a) 2-phase excitation ( $T = T_{ON} + T_{OFF}$ )

$$P_p = (P1 \times T_{ON}/T + P2 \times t_{OFF}/T) \times (1/3)$$

b) 2-3 phase excitation ( $T = T_{ON} + T_{OFF}$ )

$$P_p = (P1 \times T_{ON}/T + P2 \times t_{OFF}/T) \times (1/4) + (0.5 \times P1 \times T_{ON}/T + P2 \times t_{OFF}/T) \times (1/12)$$

### ● Power loss of Nch MOS FETs

The power loss of Nch MOS FETs is caused by the ON resistance or by the chopping-OFF regenerative current flowing through the body diodes.

(This loss is not related to the current control method, Slow, Mixed, or Fast Decay.)

The losses are

ON resistance loss N1:  $N1 = I_M^2 \times R_{DS(ON)}$

Body diode loss N2:  $N2 = I_M \times V_{SD}$

With these parameters, the loss  $P_N$  per MOS FET is calculated depending on the actual excitation method as follows:

a) 2-phase excitation ( $T = T_{ON} + T_{OFF}$ )

$$P_N = (N1 + N2 \times T_{OFF}/T) \times (1/3)$$

b) 2-3 phase excitation ( $T = T_{ON} + T_{OFF}$ )

$$P_N = (N1 + N2 \times T_{OFF}/T) \times (1/4) + (0.5N1 + N2 \times T_{OFF}/T) \times (1/12)$$

### ● Determining power loss and heatsink when SLA5017 is used

If the SLA5017 is used in an output section, the power losses of a Pch MOS FET and an Nch MOS FET should be multiplied by three and added to determine the total loss  $P$  of SLA5017.

In other words,  $P = 3 \times P_p + 3 \times P_N$

The allowable losses of SLA5017 are

Without heatsink: 5W  $\theta_j-a = 25^\circ\text{C/W}$

Infinite heatsink: 35W  $\theta_j-c = 3.57^\circ\text{C/W}$

Select a heatsink by considering the calculated losses, allowable losses, and following ratings:

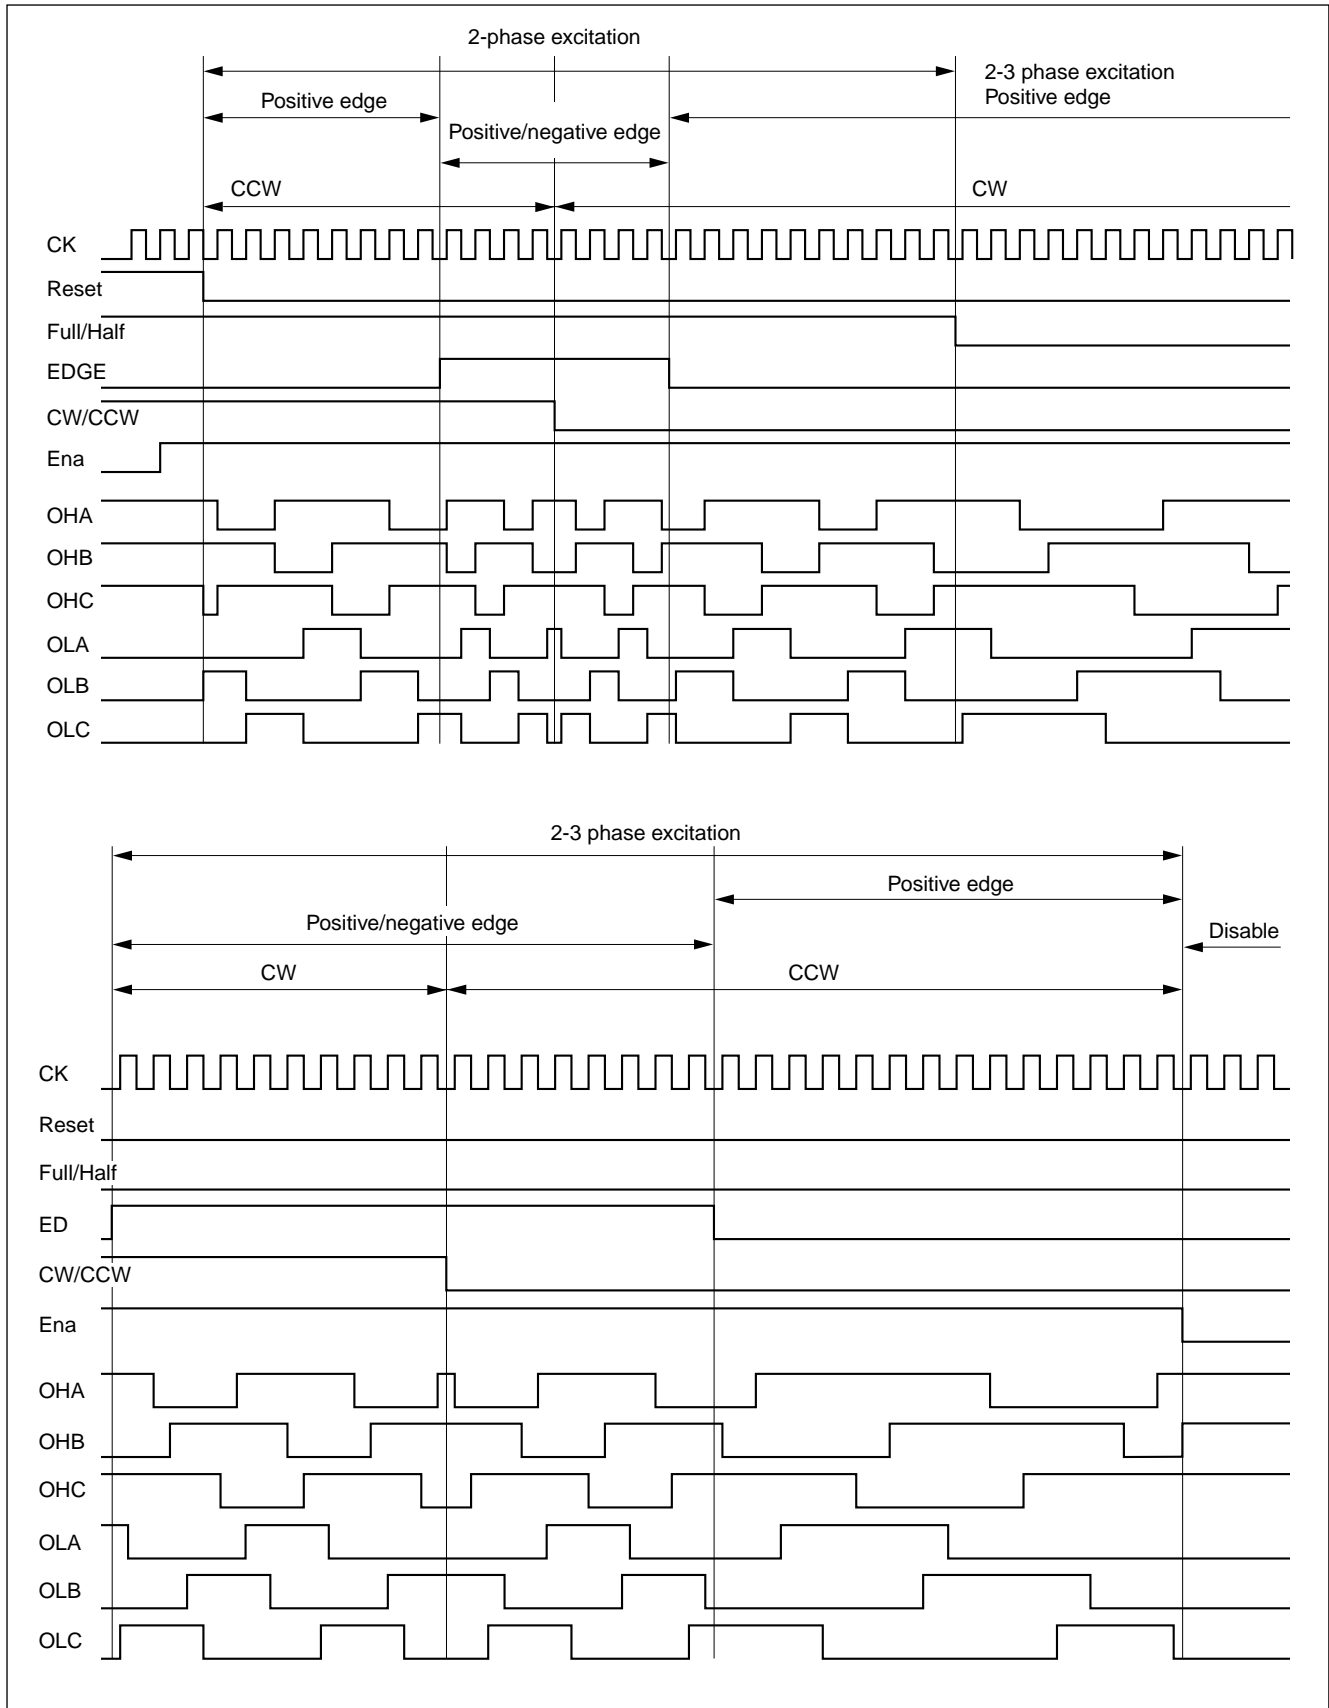

When selecting a heatsink for SLA5017, be sure to check the product temperature when in use in an actual application.

The calculated loss is an approximate value and therefore contains a degree of error.

Select a heatsink so that the surface Al fin temperature of SLA5017 will not exceed  $100^\circ\text{C}$  under the worst conditions.

# Application Notes

## ■Determining the Output Current $I_o$ (Control Current)

The main factors that determine the output current are current sense resistor  $R_s$ , supply voltage  $V_b$ , and variable current resistor  $R_x$ .

### (1) Normal mode

To operate a motor at the maximum current level, set  $R_x$  to infinity (open).

From Fig. A, when the maximum current ripple is designated as  $I_{OH}$ , its value will be,

$$I_{OH} = \frac{V_{RSH}}{R_s} \dots\dots\dots (1)$$

$V_{RSH}$  can be calculated as follows:

$$V_{RSH} = 0.19 \times V_b - 0.03 \text{ (center value)} \dots\dots\dots (2)$$

From equations (1) and (2), the output current  $I_{OH}$  can be calculated as follows:

$$I_{OH} = \frac{1}{R_s} (0.19 \times V_b - 0.03)$$

The relationship between  $I_{OH}$  and  $R_s$  is shown in Fig. B.

### (2) Power down mode

When an external resistor  $R_x$  is connected,  $V_{RSH}$  changes as shown in Fig. C even when  $R_s$  is retained. Obtain a power down output current  $I_{OHPD}$  from Fig. C and equation (1).

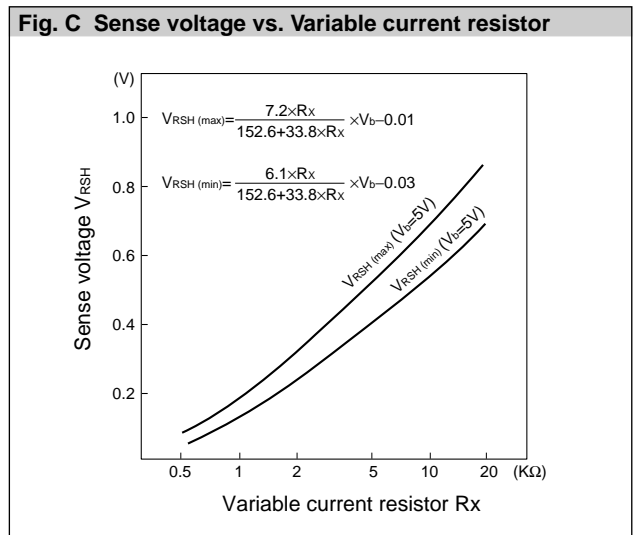

## ■Relation between Output Current $I_o$ (Control Current) and Motor Winding Current $I_{OM}$

The SI-7502 uses the total current control system; therefore, the output current  $I_o$  is different from the motor winding current. In a general pentagonal driving system, the current flows as shown in Figure D. The relation between  $I_o$  and  $I_{OM}$  is as follows:

$$I_o = 4 \times I_{OM}$$

With some driving systems, the relation can also be as follows:

$$I_o = 2 \times I_{OM}$$

## ■Motor Connection

The 5-phase stepper motor supports various driving systems and the motor connection varies depending on the driving system used.

Use of the motor with some driving systems may be restricted by patents. Therefore, be sure to ask the motor manufacturer about the motor connection and driving system to be used.

## ■Thermal design

The driver (SLA5011/SLA6503) dissipation varies depending on a driving system used even if the output currents (control current) are the same. Therefore, measure the temperature rise of the driver under the actual operating conditions to determine the size of the heatsink.

Figure E shows an SLA5011/SLA6503 derating curve. This derating curve indicates  $T_j=150^{\circ}\text{C}$ ; however, when using this device, allow sufficient margin when selecting a heatsink so that  $T_c \leq 100^{\circ}\text{C}$  (Al FIN temperature on the back of the SLA) is obtained.

SI-7502

## ■Handling Precautions

Refer to the product specifications.

Solvents- Do not use the following solvents:

Substances that can dissolve the package	Chlorine-based solvents: Trichloroethylene, Trichloroethane, etc. Aromatic hydrogen compounds: Benzene, Toluene, Xylene, etc. Keton and Acetone group solvents
Substances that can weaken the package	Gasoline, Benzine, Kerosene, etc.
