Sample calculation

- ① FM 100 kHz steps ($f_{ref} = 100 \text{ kHz}$)
FM VCO = 100.7 MHz (FM RF = 90.0 MHz, IF = 10.7 MHz)
Divisor = 100.7 MHz (FM VCO) ÷ 100 kHz (f_{ref}) = 1007 → 3EF_(HEX)
- ② AM 10 kHz steps ($f_{ref} = 10 \text{ kHz}$)
AM VCO = 1450 kHz (AM RF = 1000 kHz, IF = 450 kHz)
Divisor = 1450 kHz (AM VCO) ÷ 10 kHz (f_{ref}) = 145 → 91_(HEX)

Notes on PLL IC Usage

1. PLL IC printed circuit board patterns

① Power supply pins

A capacitor must be inserted between the V_{DD} and V_{SS} power supply pins for noise exclusion. This capacitor must be located as close as possible to these pins.

② FMIN and AMIN pins

The coupling capacitors must be located as close as possible to these pins.

③ PD pins, low-pass filter

Since these are high-impedance pins, they are susceptible to noise. Therefore, the pattern should be kept as short as possible and the area around this circuit should be covered by the ground pattern.

2. Initial states of the output ports ($\overline{BO1}$ to $\overline{BO3}$)

The initial states of the output ports after power is applied are undefined until data has been transferred.

In particular, it is possible for the $\overline{BO1}$ and $\overline{BO3}$ pins to output the internal clock, so data must be transferred as soon as possible.

However, note that the LSI cannot accept data until the crystal oscillator is operating normally.

3. VCO

The VCO circuit is designed so that it does not stop oscillating even if the control voltage (V_{tune}) becomes 0 V. (This is because the PLL circuit could become deadlocked if the VCO stopped.)
